ABSTRACT

Group liability in microcredit purports to improve repayment rates through peer screening, monitoring, and enforcement. However, it may create excessive pressure, and discourage reliable clients from borrowing. Two randomized trials tested the overall effect, as well as specific mechanisms. The first removed group liability from pre-existing groups and the second randomly assigned villages to either group or individual liability loans. In both, groups still held weekly meetings. We find no increase in default and larger groups after three years in pre-existing areas, and no change in default but fewer groups created after two years in the expansion areas.

We are grateful to the World Bank Research Committee, the National Science Foundation CAREER SES-0547898, and the Bill and Melinda Gates Foundation through the Financial Access Initiative for funding this research. We thank Tessa Bold, Jim Engle-Warwick, Karla Hoff, Kate Johnson, Jonathan Morduch, Mark Schreiner, Chris Udry, Bruce Wydick, Dean Yang, and seminar and several conference participants for comments on this project. We thank John Owens and the USAID/Philippines Microenterprise Access to Banking Services Program team for helping us coordinate the project and the Office of Population Studies at University of San Carlos for collaborating on the field work. We also thank Genevieve DeGuzman, Tomoko Harigaya, and Melissa Scudo for superb research assistance. We thank Omar Andaya, Gerald Guillen, Zaldy Mantilla, Monette Perez, and the field staff of Green Bank for implementing the experimental protocols.

I. Introduction

Group liability is often cited as a key innovation responsible for the expansion of access to credit for the poor in developing countries (Morduch 1999; Armendariz de Aghion and Morduch 2005; Microcredit Summit Campaign 2005). This contract feature purports to solve a credit market failure by mitigating adverse selection and moral hazard problems. Under group liability, clients have an incentive to screen other clients so that only trustworthy individuals are allowed into the program. In addition, clients have incentives to make sure funds are invested properly and effort exerted. Finally, enforcement could be enhanced because clients face peer pressure, not just legal pressure, to repay their loans. Thus, by effectively shifting the responsibility of certain tasks from the lender to the clients, group liability claims to overcome information asymmetries typically found in credit markets, especially for households without collateral.

Group liability could also be seen as a tax, effectively increasing the net interest rate on borrowers. This could be true particularly for individuals with stable income flows, who perhaps have the best outside alternatives for credit. Little is known about sensitivity to interest rates at the household level (Attanasio, Goldberg and Kyriazidou 2000; Karlan and Zinman 2008). Measuring the elasticity of demand with respect to group versus individual liability is important both in order to understand the net “demand” effect of this crucial loan characteristic, but also for forming credit market policy to help deepen the quantity and quality of access to finance for the poor.

The basic empirical question of the relative merits of group versus individual liability has remained unanswered for many reasons of endogeneity. Merely comparing performance of one product versus another, within or across lenders, fails to establish a causal relationship between the contract terms and outcomes such as repayment, selection, or welfare. There are countless unobserved characteristics that drive individual selection into one contract or the other, as well as institutional choices on what to offer, and how. Lenders typically chose the credit contract based on the context in which they operate. Morduch (1999) and Armendariz de Aghion and Morduch (2005) point out in their microfinance reviews that the performance of group liability contracts in developing countries indeed has been very diverse.¹

One approach is to employ laboratory experiments to help test the various theories. This has the advantage of allowing for many contract structures to be tested all at once, in the same setting. Work along these lines includes Abbink et al (2006), Cassar et al (2007), Fischer (2010), and Giné et al (2010)). Of these, Fischer (2010) and Giné et al (2010) are closest to the field setting put

forward here. Aside from these laboratory experiments, thus far we still lack good evidence on the relative importance of group liability *vis a vis* the other mechanisms, such as dynamic incentives, regular public repayments, etc. found in “group lending” schemes. Quoting Armendariz de Aghion and Morduch (2005),

“The best evidence would come from well-designed, deliberate experiments in which loan contracts are varied but everything else is kept the same.”

This is precisely the goal of the paper. We use two randomized control trials conducted by the Green Bank of Caraga in the Philippines to evaluate the efficacy of group liability relative to individual liability on the monitoring and enforcement of loans. In the first trial, half of Green Bank’s existing group-lending centers in Leyte, an island in central Philippines, were randomly converted to individual liability (but maintained their group meetings). Note that this implies that the “baseline” clients, those already receiving loans at the time of the conversion, were already screened using *group liability*. We then examine whether, after the peer screening, group liability has any additional effect on the mitigation of moral hazard through improved monitoring or enforcement. In the second trial, we worked with the Green Bank of Caraga in their expansion into *new* areas. Villages were randomly assigned to either be offered centers with group liability, centers with individual liability or centers with phased-in individual liability (centers that would start with group liability and then convert to individual liability after successful completion of one loan cycle).

The first trial allows us to separate selection from moral hazard, one of the most difficult empirical challenges when studying information asymmetries in credit markets.² The “surprise” factor of this design, created by generating a sample of borrowers that select under one contract regime but then monitors and enforces repayment under another, allows for a cleaner test of theory than offering one method to some individuals and another method to other individuals. This is useful both academically and practically in the design of products. However, it also limits the immediate policy prescriptions since the treatment conducted here strictly speaking only informs existing group liability lenders about the efficacy of switching to individual liability. However, this does not inform the lender about the relative merits of marketing and selecting clients with group or individual liability. Individuals selected under group liability may be different (e.g., safer) than those selected under individual liability. Although the analysis from this first experiment focuses on baseline (“surprise”) clients, we also present results from new members, that is, those that joined the

² See Karlan and Zinman (2007b) for an interest rate experiment which also separately identifies adverse selection and moral hazard in a South Africa credit market.

program after the removal of the joint liability clause. This allows the first trial to answer some (more limited) questions on selection as well.

This second trial, on the other hand, combines the selection, monitoring and enforcement and evaluates the overall effect of the liability on all three mechanisms. It is thus less precise in testing specific mechanisms, but more policy-relevant in that the intervention is replicable without engaging in ongoing “surprises.”

The first trial lasted three years (a total of 9 loan cycles if a client continuously borrows), and we find no change in repayment for those centers converted to individual liability, and we are able to precisely estimate this nil effect. In earlier work, with one-year results, we also found no change in repayment (Giné and Karlan 2006). We also find higher client growth in converted centers, and evidence that it is because new clients are more likely to remain in the program. In auxiliary data collected on internal procedures, we find direct evidence that individual liability leads to less monitoring of each other’s loan (although as noted, this lowered monitoring does not lead to higher default). Lastly, we find that those with weaker social networks prior to the conversion are more likely to experience default problems after conversion to individual liability, relative to those who remain under group liability. In sum, as conversions from group to individual liability become more commonplace in the microfinance community, we take an important step towards understanding whether and how such conversions work.

In the second trial, on new areas, we find no statistically or economically significant difference in repayment rates across any of the three groups. We do however find that credit officers were less likely to create groups under individual liability, and qualitatively this was reported to us as caused by unwillingness of the credit officer to extend credit without guarantors in particular barangays.

By shifting the responsibility back to the bank, individual liability will likely result in behavioral changes of *both* clients and bank staff. Both are important, and so our results should be interpreted as the net effect of both behavioral responses. We believe that the estimated net effect captures the relevant policy parameter. Furthermore, although the theoretical literature on microfinance has typically abstracted from the role of bank staff, we provide here some evidence of their behavior.

II. Background

Microfinance Trends

In recent years, some micro-lenders, such as the Association for Social Advancement (ASA) in Bangladesh, have expanded rapidly using individual liability loans but still maintaining group meetings for the purpose of coordinating transactions. Others, like BancoSol in Bolivia, have converted a large share of its group liability portfolio into individual liability lending. Even the Grameen Bank in Bangladesh, whose founder Mr. Yunus won the 2006 Nobel Peace Prize, has recently relaxed the group liability clause in the Grameen II program by allowing defaulters to renegotiate their loans without invoking group pressure. Many of these groups (e.g., ASA) have made this shift while still keeping the “group” intact. Thus, while *liability* is individualized, the group process helps lenders lower their transaction costs (by consolidating and simplifying loan disbursement and collection logistics) while possibly maintaining some but not all of the peer screening, monitoring or enforcement elements due to reputation and shame (i.e., if informal credit or risk sharing is less likely to occur if one is seen not repaying their bank loan). The group meetings have also been shown to have social benefits: Feigenberg et al (2010) find that weekly rather than monthly meetings leads to increased social interaction outside of meetings and risk sharing.

The shift to individual liability was not merely done by the Grameen Bank and a few other large, well-known lenders, but many lenders around the world are following the lead of the large, well-known lenders. Many policymakers have been advising lenders who seek to expand more rapidly (such as the Green Bank of Caraga, with whom we conducted this study) to engage in individual liability rather than group liability.

This shift from group liability to individual liability loans has accelerated as the microfinance community learns about some of the pitfalls of group liability lending. First, clients dislike the tension caused by group liability. Tension could be thought of in this context as the threat of punishment, since punishment only occurs off-equilibrium. Tension among members could be not only responsible for voluntary dropouts but could also harm social capital among members, which is particularly important for the existence of safety nets. Second, bad clients can “free ride” off of good clients causing default rates to rise. In other words, a client does not repay the loan because she believes that another client will pay it for her, and the bank is nearly indifferent because it still gets its money back. The average size of a joint liability group is 15 to 30 members. Members typically know a subset of the other members very well, but not everyone in the group, at least initially, despite the whole group being ultimately responsible for each others’ repayment. Third, group liability is more costly for clients that are good risks because they are often required to repay

the loans of their peers. This may lead to higher dropout and more difficulty in attracting new clients. Finally, as groups mature clients typically diverge in their demand for credit. Heterogeneity in loan sizes can cause tension within the group as clients with smaller loans are reluctant to serve as a guarantor for those with larger loans. In sum, while repayment may improve under group liability, outreach to otherwise profitable and credit constrained clients may be smaller, so the effect on lender's overall profitability and the poor's access to financial markets is ambiguous.

Throughout this paper we maintain an important distinction between "group liability" and "group lending." "Group liability" refers to the terms of the actual contract, whereby individuals are both borrowers and simultaneously guarantors of other clients' loans. "Group lending" merely means there is some group aspect to the process or program, perhaps only logistical, like the sharing of a common meeting time and place to make payments. The heart of this paper is testing whether the removal or absence of group liability from a "merely logistical" group lending program leads to higher or lower repayment rates, client retention and to changes in group cohesion.

Theoretical Background

The theoretical literature on joint liability builds on an earlier contract theory literature from the early 1990s that studies when a principal should contract with a group of agents to encourage side-contracts between them as opposed to contracting individually with each agent.³

In a survey article, Ghatak and Guinnane (1999) summarize the literature on joint liability by identifying four channels through which this contract feature can help institutions improve repayment: (i) *adverse selection*: ascertaining the riskiness of borrowers (Ghatak (1999; 2000), N'Guessan and Laffont (2000), and Sadoulet (2000)) or by the insurance effect that results from diversification even if borrowers do not know each other well (Armendariz de Aghion and Gollier (2000)), (ii) *ex-ante moral hazard*: ensuring that the funds will be used properly (Stiglitz (1990) and Laffont and Rey (2000)), (iii) *monitoring*: ensuring that the borrower tells the truth in case of default about her ability to pay, (iv) *voluntary default, or ex-post moral hazard*: enforcing repayment if the borrower is reluctant to pay (Besley and Coate (1995)). Group liability contracts in theory can lead to higher repayment because borrowers have better information about each other's types, can better monitor each other's investment, and may be able to impose powerful non-pecuniary social sanctions at low cost.

However, there are other theories that suggest that group liability may instead jeopardize repayment. For example, Besley and Coate (1995) point out that borrowers who would repay under

³ Examples of this literature include, but are not limited to Holmstrom and Milgrom (1990), Varian (1990) and Arnott and Stiglitz (1991).

individual liability may not do so under group liability. This situation may arise if members realize that they cannot repay as a group. In this situation, since no further loans will be granted (if rules are adhered to), members that could otherwise repay decide to default because the incentive of future credit is not longer present. This model also demonstrates that social collateral can help make joint liability work better than individual liability (barring the strategic default situation mentioned above). However, several papers have shown that group liability fails to achieve the first best allocation as well. Sadoulet (2000) argues that “social collateral” induced by group liability is not sufficient to ensure high repayment rates. Chowdhury (2005) develops a model that abstracts from adverse selection but shows that joint liability alone cannot mitigate an ex-ante moral hazard problem. In his model, either sequential lending as introduced by the Grameen Bank, where borrowers in a group do not all get the loan at the same time but sequentially, or monitoring by the lender combined with joint liability, makes group-lending contracts feasible. Despite being less efficient than peer monitoring, if monitoring by the lender is not too costly, then contracts that stipulate only monitoring by the lender may also be feasible, such as the individual liability contract of Green Bank of Caraga in the Philippines studied here (and put forward by ASA in Bangladesh), which keeps the group “logistical” aspects of the program but removes the joint liability.

Even if joint liability does not jeopardize repayment, theory also suggests it may do no better than individual liability. Rai and Sjöström (2004) show that both individual and group liability alone can be dominated by a contract that elicits truthful revelation about the success of the peers’ project. In their setup, high repayment is triggered by the ability of banks to impose non-pecuniary punishments to members according to their reports about their success and that of others. More importantly, if borrowers can write contracts with one another (i.e., side-contract), the effectiveness of group liability contracts will be limited.

Despite being the focus of much of the theoretical literature on group liability, repayment is only one outcome of interest to the lender, because the ability to retain good borrowers and attract new ones is equally important to assess overall profitability. Indeed, an institution with perfect repayment may be more profitable with lower repayment but a larger client base.⁴

⁴ In related papers, Madajewicz (2005) and Conning (2005) study when monitoring is best done by the lender and when it is best left to the peers. They both find that wealthier clients prefer individual liability loans. We cannot test the validity of this prediction because in this field experiment, loans are not backed by any form of physical collateral, so comparable (and relatively poor) borrowers are subject to one or the other form of liability.

III. Experimental Design and Data Collected

A. Trial #1: Experimental Design in Pre-existing Areas

The Green Bank of Caraga, a for-profit, regulated rural bank operating in Philippines, conducted a field experiment in which they removed the group liability component of their Grameen-style⁵ group liability program, called BULAK, in 2004.⁶ Typically a lending center starts with 15-30 individuals residing in the same barangay (community). Centers grow in size as demand increases, without predetermined maximum sizes. Within each center, members divide into groups of five. Under the normal group liability system, those in the group of five are the first layer of liability for any default. Only if those five fail to pay the arrearage of an individual is the center as a whole responsible for an individual. New members joining an existing center are also assigned into groups after mutual agreement is reached. If there are enough new members to form a new group of five, they may do so. This trial was conducted on the island of Leyte, and all 169 centers on the island were included in the sample frame.

All loans under the BULAK program are given to micro-entrepreneurial women for their business expansion. The initial loan is between 1,000 - 5,000 pesos (roughly \$18 - \$90). The increase in loan size depends on repayment of their last loan, attendance at meetings, business growth, and contribution to their personal savings. The interest rate is 2.5 percent per month, calculated over the original balance of the loan. The client has between 8-25 weeks to repay the loan, but payments must be made on a weekly basis during the center meeting.

As part of the BULAK program, clients are also required to make mandatory savings deposits at each meeting. At loan disbursement, each member deposits 100 pesos plus two percent of the loan amount into savings. In addition, each member must pay an additional ten percent of their weekly due amount (principal plus interest) into their individual savings account. Member savings may be used to repay debts and also act as collateral, although in this last case there are no fixed rules. Finally, 20 pesos (\$0.18) per meeting are required for the group and center collective savings account (10 pesos for the group and 10 pesos for the center savings accounts). The center savings cover mostly the construction of the center meeting building (a small house or hut in the village)

⁵ This is a Grameen “style” program since the bank conducts some basic credit evaluation, and does not rely entirely on peer selection. The bank’s evaluation steps include essentially two components: physically visiting the business or home to verify the presence of the enterprise and its size, and an assessment of the repayment capacity of borrowers based on the client-reported cash-flows of their enterprise.

⁶ Bulak (“flower” in Tagalog) stands for “Bangong Ug Lihok Alang sa Kalambuan”, meaning “Strive for Progress.”

and other center activities, or as a last resort to repay member loans if the center is being dissolved and default remains.⁷ The group savings is held as collateral to cover arrearage within each group.

In the first trial, the Green Bank randomly converted *existing* centers with group liability loans to individual liability loans. All other aspects of the program remain the same (including attendance at center meetings and weekly payment made in groups).⁸ Clients were also not told this was an experiment, and thus had no information from the bank to suggest that a failure to repay could lead to a reversal of the change. The only two features that changed are the group liability and the savings rules.⁹ By removing the group liability, no member is held liable for another member's default. Thus, members are no longer forced to contribute towards the repayment of other members in default and no longer required to sign as co-maker of others' loans. This allows us to isolate the impact of group liability on the mitigating moral hazard through peer pressure by comparing the repayment behavior of *existing* clients in group-liability centers and converted centers.

It is important to note that although this change removed the group liability rules, it did not remove all social influences on repayment. Group payments were still done at the weekly meeting. Although after the conversion group meetings did not include a discussion or review of who was in default, the fact that all were at the meeting provided ample opportunity for people to learn of each other's status. Thus, many clients may still repay not out of social pressure, but rather out of concern for their social reputation. One's reputation is important, for instance, in order to secure informal loans in the future from their peers, outside the scope of the lending program.

The second component of the treatment involved the savings policy. The group and center savings were dissolved and shifted into individual savings accounts. The total required savings deposits remained the same.¹⁰ With the conversion of group and center savings into individual savings, there no longer were funds set aside to pay for center activities. Thus, all center activities in treatment groups were to be paid for out of individual accounts on a per-activity basis¹¹.

⁷ In our observation, this never occurred.

⁸ Although the choice was effectively voluntary (a group could complain about the switch and remain with group liability), no group complained. Researchers often observed groups clapping when the announcement was made.

⁹ All other loan terms remained the same in both treatment and control groups, including the dynamic incentives, the interest rates, the lack of collateral, the length of the loan, the frequency of the payment, etc. If Green Bank had enforced a stricter group liability rule, the change to individual liability would also have entailed the issuing of new loans when other clients were in default. In practice, however, as in all microfinance institutions with joint liability we are aware of, loans were already being issued to clients in good standing even when other individuals were in default.

¹⁰ The new Personal Savings quota will be the previous amount of Personal Savings (based on the loan amount), plus P20, the amount previously given for Center and Group savings.

¹¹ Note that Green bank's savings policy changed in January 2006. The banks removed the group savings requirement and increased the mandatory savings toward personal savings account to 20% of weekly amortization for all clients.

Our sample includes 169 BULAK centers in Leyte, handled by 11 credit officers in 6 branches. Among these, 161 had been created before August 2004, when the experiment started. Green Bank's main competitors are NGOs (such as Taytay Sa Kauswagan, Inc. or TSKI) which mostly offer group-liability loans and cooperatives (such as the Ormoc Community Credit Cooperative Inc or OCCCI) which offer individual liability loans. At the time of the first conversion, about 28 percent of the existing centers were located in barangays with no other competitor, 53 percent of the centers were in barangays with at least one NGO and 47 percent of the barangays with Green Bank presence had at least one individual liability lender.¹²

Figure 1 shows the timeline of the first trial and data collected. In August 2004, we implemented the first wave of conversions in 11 randomly selected centers (one center per field officer). Three months later, in November 2004, we randomly selected 24 more centers to be converted to individual-liability (wave two). In the sample frame for this randomization, we included 8 additional centers formed after August 2004. Finally, nine months after wave one, in May 2005 we randomly selected 45 more centers from the 125 remaining (wave three). As of May 2007, 34 months after the start of the experiment, the final month for which we have administrative data, there are 56 converted centers and 50 original (group-liability) centers (26 converted and 37 original centers were dissolved in the past three years). Conversions were done in the three waves because of operational and repayment concerns. In particular, Green Bank wanted to assess early results to ensure default did not rise substantially before converting all centers randomly assigned to treatment.¹³ We stratified the randomization by the 11 credit officers in order to ensure a fair implementation across credit officers in terms of potential workload and risk and also to generate orthogonality to treatment with respect to credit officer characteristics. In addition, we periodically checked with credit officers and conducted surprise visits to center meetings and clients' homes to confirm that converted centers had individual liability and that control centers had group liability.¹⁴

B. Trial #2: Experimental Design in New Areas

The second trial had two important differences as compared to the first trial. First, it was conducted as part of an expansion into new geographic areas, hence individuals were informed

¹² We run separate regressions for barangays with individual liability lenders and barangays with group liability lenders. The results do not differ significantly from those of Table 5 using all barangays and thus are not reported.

¹³ Note that increased default is not necessarily bad for the bank, since the bank cares about profits not merely default.

¹⁴ Because the conversion was phased-in clients in centers converted later could have anticipated the change. To address this concern, we run separate regressions by wave and the results do not differ significantly and hence are not reported. Anecdotal evidence from credit officers suggest that clients were genuinely surprised, so anticipation effects are not likely.

whether the loan would be group or individual liability *before* borrowing. Second, there was a new experimental group, a phased-in individual liability group.

Figure 2 shows the timeline of the second trial and data collected. Credit officers in these newly established branches first conducted a market survey to identify feasible communities for Green Bank to enter. The criteria for the community selection were the same as that of pre-existing areas—the number of enterprises and economic condition to gauge potential demand for credit, safety and accessibility. Between August 2005 and August 2007, 124 barangays served by eight branches in five provinces were identified by Green Bank as feasible and randomized. The selected barangays were then visited by an independent survey team for a baseline business census,¹⁵ followed by Green Bank’s marketing activities. Out of the 124 randomized barangays, the bank opened lending centers in 68 barangays. After the business census and initial community orientations were conducted, 56 communities (45%) were deemed not feasible mainly due to lack of interest from female entrepreneurs and default or safety concerns by credit officers. We will examine this important selection issue in the analysis, given that the success of opening a center is correlated with treatment assignment.

The experimental design then randomly assigned all selected barangays into one of the three types of lending products: 1) group-liability (original BULAK program in pre-existing areas without group savings requirement), 2) individual-liability (original BULAK program, without group savings requirement nor group liability), and 3) phased-in individual-liability (group liability in the first loan cycle only, and then individual liability after successfully paying back the first loan).¹⁶ Similarly to pre-existing areas, all lending centers hold weekly mandatory meetings and payments are made in groups. If a new member joined a phased-in individual liability center after the center had already been formed, then the new member had to be accepted by all center members, and the existing members were liable for new members’ *first* loan only. Thus, the third product design tries to balance between group and individual liability: it relies on peer selection mechanism, while removing the potentially excessive peer pressure that may lead to good clients from dropping out of the program in the long run. This experiment was conducted during the bank’s three-year expansion, beginning in August 2005.

¹⁵ The baseline survey was conducted with all female household members who owned small businesses in the village. We collected information on business characteristics, revenue, household assets, demand for credit, and social network.

¹⁶ Initially, there was also a fourth group, a pure control group, which the Green Bank did not enter. The take-up rate was too low however to measure impact, and thus we decided to increase the power on the liability structure test by randomly assigning the control group to one of the three treatment groups and entering all areas, rather than maintaining one no-credit control group.

C. Data Collected

The first experiment, in pre-existing areas, uses data from five sources. First and most importantly, we use the Green Bank's full administrative data on repayment, savings, loan sizes, number of clients, and client retention rates. We have the data for all 3,285 clients who were active members of the 161 centers at the time of the first randomization in August 2004, as well as the eight new centers opened after August 2004 under group liability and then included in the second randomization wave. We use the data from one year prior to the first wave of the experiment to 24 months after the last wave of experiment, thus enabling us to incorporate center-level fixed effects in our analysis with pre and post observations. Second, we use the data from an activity-based costing exercise that credit officers conducted, where for a given week, they had to keep a log of how they allocated their time across the different tasks they typically perform (e.g., attending meetings, assessing new clients, enforcing repayments, etc). The data were collected in January 2006. Third and fourth we use the data from a baseline and follow-up social network survey, conducted in November 2004 and January 2006.¹⁷ Finally, we use a survey of clients in pre-existing areas designed to understand the observed differences between converted and control centers. This survey was conducted in November 2005 (about one year after the start of the experiment in pre-existing areas) and asked about loans from other lenders and clients' knowledge on businesses and repayment performance of other members. The second experiment, in new areas, uses four sources of data. First, we use the complete administrative data for all 68 centers in new areas from the time of center establishment up to May 2008. Second, prior to Green Bank's program introduction in treatment villages, we conducted a census of all households with enterprises. Third, we conduct an activity-based costing exercise in July 2008 that is similar to that conducted in the first experiment. Fourth, we conducted a social network survey of the initial members of each formed center. These social network surveys were collected by credit officers during the first center meeting. Unlike the first experiment, due to budgetary reasons we did not conduct a follow-up social network survey, nor an activities survey about specific monitoring and enforcement activities in each center.

Table 1A presents summary statistics and orthogonality checks for the clients and communities in the conversion areas sample. It shows that the randomization yielded observably similar treatment and control groups, when treatment groups are pooled in pre-existing areas. This holds when we examine group-level measures (Panel A) as well as individual level measures (Panel B). Table 1B presents summary statistics for the second experiment. Panel A and Panel B verify

¹⁷ Note the social network baseline was conducted after the first wave of conversions but before the second and third waves, hence the social network analysis will not include the first wave of the sample frame.

that the initial randomization in new areas also created assignment groups that are similar in village characteristics, in nineteen out of the twenty tests reported in Columns 5 and 6.

IV. Empirical Strategy and Primary Results

We test several hypotheses that emerged in the previous discussion of the relative merits of group versus individual liability. We organize the results by question, and then within each question we first show the results for the pre-existing areas (the first experiment) and then for the new areas (the second experiment). The first analysis uses the individual loan-borrower as the unit of observation, and examines the impact on key variables that affect bank profitability, such as repayment, savings deposits held at the Green Bank by borrowers, and loan size (Table 2A and 2B). Then we analyze client drop-out (Table 3), client retention, and success in attracting new clients, as well as loan portfolio at the center level (Table 4A and 4B). All of the above analyses are conducted with the bank's administrative data. Then we examine the difference in the costs of managing individual versus group liability centers, using the data from activity-based cost exercises (Table 5). The rest of the analyses use the survey data on social network, other loans, and members' knowledge about repayment performance of others. We analyze the mechanisms through which activities changed within the bank in pre-existing areas; this provides evidence of the experimental design being implemented as designed, and also evidence of specific peer screening, monitoring and enforcement activities (Tables 6 and 7). Then we examine heterogeneous treatment effects by social network on default (Table 8) as well as impacts on social networks themselves in pre-existing areas (Table 9 and 10). Lastly, we test the treatment effect on the strength of social network in newly established centers in expansion areas (Table 11).

Throughout the analysis of the first experiment, we define a "treated" loan to be one that matures after the conversion from group to individual liability. In other words, we consider loans that have any exposure to individual liability as treated loans.¹⁸

Table 2A Panel A presents the primary results for the first experiment. The specifications use individual loan cycle level data, with standard errors clustered at the center level, the unit of randomization. The sample frame includes only clients that were borrowers at the time of the initial randomization. This allows us to focus analytically on the *ex-post* changes in behavior generated by group versus individual liability, holding constant a sample frame of individuals screened under a group liability regime.

¹⁸ Alternatively, the treated cycle could be defined as all loans released after the conversion. Results are robust to this alternative definition of treated cycle.

Specifically, we estimate a difference-in-difference (using pre-post and treatment-control data) model using OLS:

$$y_{ict} = \alpha + \beta T_{ct} + \delta_t + \theta_c + \varepsilon_{ict},$$

where the subscript i refers to the individual, c the center, and t the time period, T is an indicator variable if center c is under an individual liability regime at time t , δ_t are time fixed effects and θ_c are center fixed effects. Thus, β is the coefficient of interest.

Table 2 (Panel A, Columns 1 through 6) shows that the conversion to individual liability had no adverse effect on repayment for the baseline clients, regardless of the measure of default. Given that the default rate is very low, the impact of conversion can be seen as a one-sided test, where at best there is no increase in default. Not only is the point estimate close to zero, but most economically significant effects can be ruled out: the 95 percent confidence bound on proportion of loan balances in default at the time of maturity (Column 3) is $-0.1\% \pm 0.2\%$ and the 95 percent confidence bound on the likelihood of any default 30 days after maturity (Column 6) is $-1.1\% \pm 2.2\%$. Thus, we do not find strong enough evidence to support the “social collateral” story of Besley and Coate (1995) that predicts higher repayment for group liability loans on average.¹⁹ However, as noted elsewhere, the conversion to individual liability does not remove all “social collateral” since repayment is still public, and someone may repay in order to protect their reputation in the community.

Table 2 Panel B shows similar results for the *new* clients. In this sample frame, selection is confounded with monitoring and enforcement. Yet even here, those selected under individual liability and given individual liability loans are also no more likely to default than those selected under group liability and given group liability loans. The 95% confidence bounds also allow us to rule out economically large effects, although they are slightly larger than those for the baseline clients in Panel A. The second experiment, in new areas, will speak to this question as well, and find similar (null) results.

Table 2 Columns 7 and 8 show savings behavior and loan sizes for both baseline and new clients. We find a reduction in voluntary savings (i.e., savings over and beyond the required cash collateral they have to pay along with loan payments) and a reduction in loan size for all clients. One may have expected higher savings in individual liability since the savings deposits were not held as collateral for other people’s loans: the expected return on savings is higher under individual

¹⁹ Below, we will examine heterogeneous treatment effects (Table 9) where we will find evidence that default increases for those with lower baseline measures of social collateral.

liability (assuming there is some default in expectation under group liability).²⁰ Greater reduction in loan sizes on new clients under individual liability could be due to several mechanisms: an indication of the selection of new entrants (poorer individuals were screened out under group liability, and are now able to join); more restrictive lending by credit officers, and/or lower appetite for larger loans since borrowers no longer rely on the implicit insurance that group liability provides. In qualitative interviews, credit officers deny that they restricted loan sizes of clients under individual liability centers. Instead, they told us anecdotally a different story: savings accumulated more quickly for the clients in converted centers (because the required personal savings increased) and so they decided to withdraw it for various purposes at the end of the loan cycle—this, in return, lowered their capacity to borrow in the subsequent loan cycles. While this may not be a favorable outcome for the bank profits, the client welfare under individual liability may have increased if they used more savings and borrow less. However, we do not have quantitative data to provide strong evidence to support a particular mechanism.

The conversion to individual liability implies both a reduction in peer pressure and a potential increase in bank pressure to repay (see Chowdhury, 2005). The above empirical analysis concludes that the net effect is nil. To confirm that in fact the conversion was adhered to and group liability was not imposed in the treatment centers, we ask current members the reason that others left. Appendix Table 1 shows these results. Under individual liability, individuals are less likely to be forced out of the center in net (Column 1), but importantly Column 2 shows that individuals are less likely to be forced out by their peers and more likely by the credit officer. This could be simply a bookkeeping effect, or could be capturing a behavior change by the credit officer as they worked harder to screen out defaulters. Credit officers did perceive a bonus based on maintaining a high repayment rate. Credit officers also may have changed their behavior with regard to enforcement of project choice, i.e., trying to force borrowers to take on safer projects in response to the shift to individual liability. In the November 2005 follow-up survey, we collected the type of business and weekly sales, but we cannot reject equality across treatment and control. We also test whether the variance of sales differs between treatment and control centers, and also cannot reject equality.²¹ In addition, it is not part of the training of credit officers (either before or after the experiment) to engage in discussions with the clients about how they are investing their funds and so this seems an unlikely explanation for the findings.

²⁰ This assumes that the substitution effect is larger than the income effect for savings elasticity.

²¹ Type of business and the standard deviation of weekly sales are only proxies for the underlying borrower riskiness. We consider the measurement of riskiness an important question, but for which we still lack a convincing methodology.

We now turn to the second experiment, on new areas. Table 2B presents the primary results. The specifications use individual loan cycle level data, with standard errors clustered at the center level. Because the second trial took place in expansion areas and there is no pre-intervention data, we simply compare the post-intervention outcomes across treatment and control groups, using the credit officer and time fixed effects. Table 2B Panel A shows the average effects of all loans. Similarly to the pre-existing areas, the coefficients are close to zero and not statistically significant.

Table 2B Panels B and C show the same analysis separately for the first cycle loans and repeat loans. The results in Panel B are consistent with the overall analysis in Panel A—coefficients are small and not statistically significant, indicating that there is no difference in repayment performance across group, individual, phased-in individual liability clients. Table 2 Panel C shows that repeat loans under individual liability actually have a *lower* probability of defaulting by 3 percentage points at the 30 days after maturity date (Column 6), although this is the only significant result out of six measures of default, and two sample frames, and thus this result is not robust.

Table 3 uses a Cox proportional hazard model to estimate the likelihood of dropout in both pre-existing and new areas. While in pre-existing areas we find that the baseline clients are slightly *more* likely to stop borrowing as a result of conversion to individual liability, for new clients we find the opposite: those under individual liability are *less* likely to stop borrowing (Table 3 Panel A). Table 3 Panel B shows the results in new areas. There is no significant difference (both statistical and in magnitude) in the likelihood of clients' dropout between clients under individual and group liability, while clients under phased-in individual liability are significantly less likely to drop out. Dropout as an outcome variable is naturally ambiguous: from a borrower's perspective this could be a sign of success, that the loan successfully addressed their cash needs in the enterprise or their personal life and they no longer need credit. Or, alternatively, and especially for new clients, dropout could be a sign that once in the program the client learns that it is not good for them, that it causes issues in their personal life, social life, or business to have the debt burden.

Table 4A examines the main outcomes at the center level in pre-existing areas. We estimate the following specifications using OLS:

$$y_{ct} = \alpha + \beta T_{ct} + \delta_t + \theta_c + \varepsilon_{ct},$$

where y_{ct} is either center size, retention rate,²² new accounts, number of dropouts, total loan disbursement, or center dissolution for center g at time t , δ_t is an indicator variable equal to one for time period t (time fixed effect), θ_c is a center fixed effect, and T_{ct} is an indicator variable equal to

²² The retention rate between t and $t+1$ is defined as the percentage of clients at t that are still clients at $t+1$.

one if center c at time t had been converted to individual liability. The time fixed effects refer to three-month time periods (since individuals within centers do not get issued loans at the same time). The coefficient of interest is β . We test whether the liability rule matters by examining whether the coefficient β is significantly different from zero. Note that here, since the unit of observation is the center (at a certain point in time), we use information from *all* clients who belonged at each point to the center between August 2003 and May 2007.

We find that individual liability is much better at attracting new clients (Panel A, Column 2), leading to larger centers (Column 1) and that individual liability makes existing centers 13.7% points less likely to be dissolved (Panel B Column 2). This final result is the largest, and has important practical implications, since dissolution of groups after two to three years is a commonly cited concern among microfinance institutions.

Table 4B shows the center-level analysis on institutional outcomes in the second experiment. The center-level analyses are also conducted with all loans (Panel A), first cycle loans only (Panel B), and repeat loans only (Panel C). Since 46% of the villages randomized were not entered by Green Bank, the analyses on active accounts and loan disbursement are conducted for villages successfully entered by Green Bank (Columns 1 and 4) as well as for all villages randomized (Columns 2 and 5). While there is no significant difference in the center size and total loan size at the center-level across three product groups when restricting the analysis to the villages entered by Green Bank, the analysis with all randomized villages including those not entered by Green Bank show that the center size is significantly smaller on average for both individual liability and phased-in individual liability groups. This is a consequence of either Green Bank staff reluctance or inability to enter villages assigned to individual liability and phased-in individual liability (see discussion in next section). A village-level regression on the likelihood of Green Bank entering (Panel C) confirms that Green Bank was less likely to enter the villages assigned to individual or phased-in individual liability on average, although this effect on individual liability is not statistically significant.

V. Additional Results on Specific Mechanisms

We now turn to four sets of auxiliary data.²³ First, we examine the results of the activity-based costing exercise for both experiments completed by the credit officers in order to measure the change in their allocation of their time across centers. Second, for just the first experiment, we examine the results of a client follow-up survey conducted in November 2005 (over one year after

²³ These auxiliary results from the first experiment were previously reported in an unpublished working paper (Giné and Karlan 2006), but are being absorbed into this paper in order to provide a richer set of tests of mechanisms and policies.

the initial conversion) on clients in both the treatment and control groups. This survey questions were designed to tell us more about three possible mechanisms that could be influenced by the liability structure: center activities, selection and the flow of information (monitoring). The survey was conducted during center meetings and was administered using a stratified random sampling from 1) baseline clients, 2) clients who joined the program over the three months prior to the survey, and 3) clients who dropped out within the three months prior to the survey.²⁴ Third, for the first experiment we use social network data collected before the intervention and again one year later to examine the impact on social networks, as well as heterogeneous treatment effects for groups with different preexisting levels of social networks. Fourth, for the second experiment, we use baseline social network data to examine how screening differed across treatment groups.

A. Lender Costs: Activity-Based Costing Exercise

The introduction of individual liability is also likely to affect lender behavior. The lender may spend more resources on credit officer labor in order to screen, monitor and enforce loans. In order to evaluate to what extent individual liability led to changes in credit officers' effort, we conducted an activity-based costing exercise in which each credit officer kept a detailed diary of all activities for one week. We then attributed their activities to either repayment (preparing for center meetings plus collection and processing of repayments outside of the meetings), center meeting, monitoring, enforcement and/or re-loan activities. Table 5 Panel A and Panel B report these results in pre-existing areas and new areas respectively. In pre-existing areas we find no statistically significant differences in the way credit officers allocated their time, and furthermore the point estimates are actually the opposite of what one may have expected on enforcement. On approval and processing of new loans (Column 3), credit officers do spend more time under individual liability, although again this result is not statistically significant. On the other hand, in new areas credit officers spend more time on repayment activities (center meetings) in individual liability centers than in group liability centers. There are no statistically significant differences between time spent in phased-in individual liability centers and group lending centers. Although not statistically significant, the shifting of time from marketing to repayment activity is consistent with the lower probability of forming an individual liability center discussed above. More importantly, we may fail to see a difference in repayment across treatment groups in new areas (Table 2B) precisely because

²⁴ Since meeting attendance is compulsory, we should not be concerned with having a biased sample of survey respondents. In any event, compared comparison of past repayment between respondents and non-respondents in converted and control centers yields no statistical differences across samples (largest t-stat is 0.82).

the credit officer is deliberately spending more time in repayment activities of individual liability centers.

B. Center Activities, Survey Results from First Experiment

The client follow-up survey asked questions about center penalties for missing meetings, leaving early and missing payments as well as various activities such as anniversary, Christmas and snacks during the meeting. Table 6 reports changes in penalties (columns 1 and 2) and activities between treatment and control centers. We find that treatment centers impose lower penalties, possibly because meetings run smoother now that there is less need to enforce peer pressure among clients. However, the conversion to individual liability may have resulted in lower center cohesion as evidenced by the lower probability of social events (not significant) and the lower amount spent (significant for Christmas parties).

C. Selection and Monitoring, Survey Results from First Experiment

Four sets of analysis provide insight into the changes in the selection of clients and monitoring resulting from the change in liability. We asked each member how well they knew the new members that had joined the center since intervention began. Table 7 Columns 1 and 2 show these results. We find that the prior members are *more* likely to know new members well under individual liability than under group liability. This is striking, given the typical assumption that group lending programs encourage peers to screen each other. However, this is consistent with evidence that the depth of family relations within a group is correlated with default (Ahlin and Townsend 2007). Under individual liability, peers no longer fear the acrimony of having to punish someone close to them if there is default, and hence are more willing to invite in their closest friends and family. New members, on the other hand, are *less* likely to know the other new members. Since new members are typically not the ones who bring in new members, this indicates that groups are making fewer *group* decisions on whom to admit and instead individuals are inviting their close friends or family. Thus prior members are closer to the new members, and new members are more distant to the other new members. This is also consistent with the fact that new members in treatment centers are less concerned with screening and monitoring other new clients.

Second, we examine how well individuals know the “type” of the other members in the group. We report these results in Table 7 Columns 3-12. We asked each individual five questions: (1) What is the business of person X? (Columns 3 and 4), (2) What is the required installment amount for person X? (Columns 5 and 6), (3) How many weekly installments did person X miss over the past three months? (Columns 7 and 8), (4) Did person X miss any payments over the past three months? (Columns 9 and 10), and (5) Do you think person X will miss some payments over

the next three months? (Columns 11 and 12). We do not find any change in ability to report the peers' businesses, but we do find *lower* levels of ability to report who has missed payments (hence suggestive evidence of reduced monitoring, although also explained by simply not having to participate in repaying that person's missed payments) and lower levels of ability to *predict* who will or will not default. Again, this is evidence of lower monitoring, since it implies individuals are less informed about the status of each other and, hence, their ability to repay their loans.²⁵

The third result on selection looks at the distribution of ability to pay (rather than observed repayment) among existing clients and new clients in treatment and control centers. We asked how many times in the last 3 months they had difficulty in repaying the loan, regardless of whether or not they ended up completely repaying the loan installment. This measure (rather than observed default) captures the combination of "type" (selection) and ex-ante moral hazard (effort) that is generated from group versus individual liability because being in default is only observed when the member does not have enough cash *and* other members fail to contribute toward the installment. Since side contributions are compulsory in control centers but only voluntary in treatment centers, differences in default rate would come from not only different ability to repay but also different contribution levels from fellow group members.

In a world where creditworthiness is verifiable through a costly screening process, there are two groups of borrowers that would only join individual liability centers. On one end of the creditworthiness distribution, bad risks would be screened out and rejected from group liability centers, but could be allowed into individual liability centers because current borrowers lack the incentive to screen (and the lender may be unable to screen as effectively as the peers). On the other end of the distribution, good risks may have little to gain and much to lose from the implicit tax imposed by group liability. They decide not to join group liability centers because they fear being forced to help other members repay more frequently than they will receive help. Yet, they join individual liability centers because repayment only depends on their performance. The left panel of Figure 3 plots the distribution of the number of times new clients had difficulty making their payments, while the right panel plots the same distributions for baseline clients (those borrowing at the time of conversion, hence screened under group liability). Interestingly, the distributions of baseline clients in treatment and control centers look alike, but the distribution of new clients is more concentrated around zero in treatment centers than in control centers. This suggests that good risks were reluctant to join group liability centers but do so after these centers are converted to

²⁵ Note, Chowdhury (2005) and Ghatak and Guinnane (1999) use the term monitoring to denote information about project choice, while we measure knowledge about missed payments, perhaps closer to auditing.

individual liability. We do not find evidence of bad risks also joining individual liability centers. A Kolmogorov-Smirnov test of equal distributions between treatment and control centers is rejected at 10 percent for new clients but not for baseline clients.

The fourth and last result on selection focuses on the interaction between demand and the competitive setting. Did individuals increase or decrease their borrowing with other lenders after the Green Bank converted to individual liability? The results are reported in Table 8, where it is clear that the answer depends entirely on whether the other lender is a group or an individual liability lender. If we restrict the analysis to barangays in which the competition is engaged in *group* lending, then we find that baseline Green Bank clients are more likely to borrow from them after their group is switched to individual liability. This indicates perhaps that *some* individuals among baseline clients prefer group liability (perhaps for the risk-sharing component of group liability) and hence when the group liability is removed they remain with the Green Bank but also then seek a loan from a separate group liability program. On the other hand, when the competition only offers individual liability, we see a *reduction* in the likelihood that baseline clients seek a loan (although this result is only significant in the tobit specification on loan size, and has a p-value of 0.17 for the probit specification). This indicates that when the Green Bank switches to individual liability, individuals who prefer individual liability are more satisfied, and individuals who prefer group liability seek supplementary loans from other group lending programs. Results are less conclusive for the new clients, perhaps due to the lower sample size.

D. Heterogeneous Treatment Effects with respect to Social Networks

Theoretically, the shift to individual liability may have worked better or worse in groups with different levels of preexisting social networks. If social collateral keeps repayment high, then “releasing” the collateral by converting to individual liability (and replacing the social collateral with bank pressure and mere public disclosure of default, but not group liability) may lead individuals with higher social capital to have lower repayment rates. On the other hand, if individuals have higher social capital because of their stronger and more trustworthy characters, then the shift to individual liability should be less likely to influence their decision to repay (since they are a “trustworthy” type, perhaps irrespective of whether social collateral is at stake or not).

We test the net effect of these possible mechanisms in Table 9 by interacting treatment with one of various social network measures. The social network data were collected during the center meetings in between the first and second wave of the randomization (for this reason, the first wave centers are removed from this analysis, since their “baseline” occurred *after* the treatment began). The survey procedure was simple: in public, in the meeting, a surveyor asked an individual to stand

up and then asked all other members in the group to raise their hand if their answer to a specific question about their relationship with this person was “yes.” This method prevents one from asking highly personal questions (e.g., “Would you lend to X if they asked you?”) but does allow for higher precision on questions which are of public knowledge (since one has the attention of everyone in the group to facilitate answering the questions). We categorize the social network questions as either “knowledge” or “trust”. “Knowledge” includes: family, friend since childhood, buys products or services, or visits once a week for social purposes. “Trust” includes has given a loan to the other person outside of the Green Bank program, voluntarily helped them pay their Green Bank loan, or turns to this person for advice or help.²⁶

We then examine the primary repayment measure: percentage of loan past due at the time of maturity. We find that default is lower for those with *stronger* social networks relative to those with weaker social networks. This is true both for “knowledge” measures of social capital (Column 5) and the pooled aggregate index (Column 10), but not for the “trust” measures (Column 9).

These results may be an indication that those identified as having stronger “trust” social networks are in fact a more trustworthy “type,” hence the shift to individual liability has no adverse effect on their likelihood of repaying. In other words, being “trustworthy” is a personal characteristic that determines ones social networks and also leads to higher repayment of loans. This is consistent with results from Karlan (2005), in which trustworthy behavior in a lab experiment in the field predicted repayment of loans one year later to a microcredit organization in Peru. An alternative hypothesis is that those with stronger social networks must repay their loan in both setups in order to protect their social networks. Those with weaker social networks have less to lose from the “shame” of being seen in default (less social collateral, in the model of Besley and Coate (1995)), and hence the shift to individual liability generates higher default. Of course, we cannot say conclusively why this result is heterogeneous, but it does suggest that the existing literature on the link between social capital and repayment within group lending is an important literature, and that more needs to be learned about the circumstances under which social capital helps versus hurts both the repayment and growth in lending programs.

E. Impact on Social Networks, Conversion Areas Only

Next, we examine how the liability structure affects the social network among center members in both conversion and new areas. In Table 10 we show the results of the analysis on changes in social network in pre-existing areas. As we have both baseline and follow-up data on

²⁶ The use of these questions is becoming standard. For other examples, see Ambrus et al (2009), Attanasio et al. (2009) and Giné et al. (2009).

social networks, we are able to employ a difference-in-difference empirical specification. We find only one social network channel to have changed: likelihood to help another person with a side-loan in order to help her make her loan payment. Social networks could change under individual liability relative to group liability for many reasons. First, with fewer incentives to monitor, the *quantity* of interaction may fall (e.g., in that vein, Feigenberg et al 2010 find higher frequency meetings leads to higher risk-sharing). On the other hand, the *quality* of the interaction may increase since they no longer have to pressure each other to repay. From selection, as found earlier, we find groups more connected because individuals are inviting closer friends and family to join the center. However, in net, we find no significant impacts on social networks, except the reduction in side loans.

F. Selection Effects with Respect to Social Networks, New Areas Only

When entering into new areas, we examine how the liability rules influence the social capital that exists amongst the initial members. The theoretical prediction is ambiguous. One may expect group liability centers to have stronger social network, because members are directly held liable for other members' loans. Alternatively, if group liability imposes excessive pressures on members, close friends and neighbors may be more likely to join individual liability centers, where they do not have to risk their social capital. Table 11 presents the effect of the liability structure on the social networks amongst those who borrow. The results show that there is no consistent and significant difference in the social network among center members across group, individual, phased-in individual liability centers, with the exception that those who join individual liability centers have a lower average proportion of members who know other members since childhood. This is consistent with the finding in conversion areas that new members were less likely to know each other well, but since this is the only one of five social network measures that finds a difference, we consider this result suggestive at best.

VI. Conclusion

The choice of group or individual liability is perhaps one of the most basic questions lenders make in the design of loan products in credit markets for the poor. Despite the importance of this decision, past empirical research on group and individual liability has not provided policymakers and institutions the clean evidence needed to determine the relative merits of the two methodologies. In this study, we use two randomized control trials to evaluate the impact of group liability on the performance of clients and the profitability for the lending institution. Naturally, these are from one lender in a few regions of the Philippines, but this is a transition we are witnessing around the world. As with all empirical research, many questions persist as to whether these findings will hold in other countries, in other cultures and with other lenders, and in particular

whether theory that incorporates the underlying level or structure of social capital, e.g., can predict successfully whether group or individual liability will perform better. Although this decision by the bank to shift from group to individual liability is becoming more commonplace, we still must ask whether the culture or macroeconomic conditions, for instance during the three year time period of this study, led to similar outcomes for both individual and group borrowers, and whether under different external conditions differences in repayment would arise. Social science, just like physical sciences, needs replication, along with theory, in order to solve these issues.

The results are striking, however, in three respects. First, we find that individual liability compared to group liability leads to no change in repayment but did lead to larger lending groups, hence further outreach and use of credit, for pre-existing groups. Second, in new areas, we found bank officers *less* willing to open groups despite no increase in default. Thus the supply constrained the growth of the lending program, whether for good cause or unwarranted fear by the employee is outside the scope of our data to assess. Third, we do find statistically significant evidence of some of the *mechanisms* discussed in the group liability literature, such as screening and monitoring, but we simply do not find that it adds up in an economically meaningful way to higher default.

One could argue that the results from the first experiment lend support to the adverse selection story of Ghatak (2000) because borrowers that selected into the program under joint liability would tend to be safer. The finding that after the removal of group liability monitoring goes down but repayment does not change, suggests, at the very least, that peer monitoring or peer pressure are unimportant. However, the lack of default for *new* members too suggests that the answer is not that straightforward, that even new clients brought into centers built under group liability repay their loans. This could be a result of group liability creating well-functioning groups, and even new members adhere to the practices and policies of the pre-existing members.

The larger new centers, combined with the lack of increased default, suggest that the screening process has changed without worsening repayment. The findings seem consistent with the model of Chowdhury (2005), where the removal of group liability has probably resulted in an increased monitoring and screening done by credit officers, although we did not find an increase in their workload.

Our findings are also consistent with the work of Greif (1994) in a rather different context. He suggests that collectivist societies, like joint liability institutions in our setting, are based on the ability to impose social sanctions to players that deviate from the agreed norms of conduct. But this requires a level of trust and knowledge among players that may hinder expansion of the set of players thus leaving efficient trades unrealized. A more individualistic society requires fewer

exchanges of information among players and is thus able to grow faster. It does necessitate, however, well-functioning formal institutions to enforce contracts. In our context, shifting some of the burden from clients to credit officers strikes this balance successfully. The institutional enforcement is sufficient to recover loans without group liability, and the individual liability allows for more growth and outreach for the lender.

In sum, the recent trend of microfinance institutions expanding their individual lending products (or in some cases, shifting from group liability to individual liability but maintaining group meetings) may help deepen outreach and provide more flexible microfinance products for the poor. Our findings suggest that the innovators finding methods of lending individually (and more flexibly, see Karlan and Mullainathan 2009) to the poor may be moving in the right direction.

Figure 3: Kernel Density: Number of weeks that clients had difficulty repaying 3 months prior to the November Survey, Center average

The left panel shows the kernel densities of the center average of the number of weeks in difficulty repaying over the three months prior of the survey in November 2005 for treatment centers (red) and control centers (blue). The right panel plots the same distribution for baseline clients. The sample includes clients who attended the center meeting when the survey was conducted.

Number of active clients, August 2004	3,285	1,708	1,577		298	394	885	

Standard errors in parentheses. In Panel A, the number of active centers is less than 169 in August 2004 because there are 8 centers that started after the first conversion and added to the sample. P-values reported in column (4) are the probability of (column (2) - column (3)) being zero. P-values in Column (8) are the probability that each treatment wave are jointly equal to zero. The associated F-statistic comes from a regression of the outcome variable of interest on a set of indicator variables for each of the treatment waves. The exchange rate at the time of the experiment was 52 pesos = US\$1.

Robust standard errors clustered by lending centers in parentheses, * significant at 10%, ** significant at 5%, *** significant at 1%. Treatment variable equals one if the loan cycle ends after the conversion in treatment centers; zero otherwise. All regressions use fixed effects for each credit officer and month of the maturity date. The sample frame for Panel A is baseline clients, i.e., those who were active at the first conversion in August 2004; the sample frame for Panel B is new clients, i.e., those who joined the program after August 2004 in the control group or after the conversion in each of the treatment groups. Proportion of missed weeks is calculated by the number of weeks in which the client did not make the full installment divided by the number of installments. Total excess savings is defined by the excess amount of savings that the client deposit beyond the required savings amount over a loan cycle (the value takes zero if the total deposit does not reach the required savings amount).

Robust standard errors clustered by lending centers in parentheses, * significant at 10%; ** significant at 5%; *** significant at 1%. All regressions use fixed effect for credit officers and months of maturity dates. Panel A reports on all loan cycles, Panel B uses the first loan while Panel C uses subsequent loans.

Table 3: Impact on Dropout

Cox proportional hazard model, failure = dropout

Dependent Variable: Binary variable equal to one if the client has dropped out

	(1)	(2)
Panel A: Conversion Areas		
	Sample frame: <u>Baseline clients</u> <u>New clients</u>	
Individual liability	1.121*	0.857***
	(0.071)	(0.042)
Observations	8310	7157
Panel B: New Areas		
	Sample frame: <u>All clients</u>	
Individual liability	0.973	
	(0.48)	
Phased-in individual liability	0.794***	
	(3.31)	
Observations	3610	

* significant at 10%; ** significant at 5%; *** significant at 1%. The model estimated is the Cox proportional hazard. Reported are hazard ratios and standard errors in parentheses, calculated assuming within-center clustering. Lower hazard ratio (<1) indicates that clients in Treatment centers stay longer in the program and that conversion into individual-liability is associated with lower likelihood of dropping out.

Table 4A: Institutional impact At the Center Level, Conversion Areas

OLS, Probit

Mean of dependent variable	0.03	0.37					
Observations	2017	169					
Number of centers	169						
R-squared	0.080						

Robust standard errors in parentheses, * significant at 10%; ** significant at 5%; *** significant at 1%. "Treatment" is an indicator variable equal to one if the center has been converted for a given observation. All regressions except Panel B, Column 2 use fixed effects for credit officers and months of maturity dates, and standard errors are clustered by lending centers. Every center has an observation on each outcome for every three month between August 2003 and May 2007. Panel B, Column 6 uses fixed effects for credit officers and reports the marginal effects for the coefficient on treatment. Total loan amount is the aggregated loan amount disbursed in a center, and average loan amount is the average loan size per client. Both numbers are in pesos (1 US \$ = 52 pesos). Panel A, Columns 2-4 excludes centers that had been dissolved in the previous time periods; The sample for Panel A, Column 1 is active centers in which there are matured accounts in each time period.

Robust standard errors in parentheses, * significant at 10%; ** significant at 5%; *** significant at 1%. Regressions in Panel A use fixed effects for credit officers and months of maturity dates, and standard errors are clustered by lending centers. In Panels A and B, every center has an observation on each outcome for every three month between September 2005 and August 2008. Regressions in Col (1) - (3) in Panel A and B control for the number of active accounts in the previous time period.

Table 5: Activity-Based Costing Analysis: Time Spent on Different Activities by Center

	OLS						
	Time on expansion (1)	Time on reloan (2)	Time on expansion/reloan (3)	Time on repayment activities (4)	Time on loan monitoring (5)	Time on following up with delinquent clients (6)	Time on loan enforcement (7)

R-squared	0.201	0.207	0.208	0.290	0.418	0.245	0.171

Robust standard errors in parentheses. * significant at 10%; ** significant at 5%; *** significant at 1%. All regressions use fixed effect for credit officers. Each cell reports the average time in minutes spent on indicated activity per center in a given week in January 2006. Expansion includes marketing activities, orientation for potential clients, and conducting trainings for new clients. Reloan includes conducting credit evaluation, filing/reviewing of loan forms, and releasing the loan. Repayment includes preparing for center meetings, travel time, center meetings, and handling the collection. Monitoring involves making reports, answering clients' questions; enforcement includes loan utilization check and following up with delinquent clients.

Table 6: Center Activities, Conversion Areas

Sample framework: Wave 2 and 3 Centers Only (because data collected during social network survey)

	Anniversary			Christmas parties		
	Total enforced penalties		No activity	Likelihood of having a party		Amount spent, conditional on having a party

R-squared	0.09	0.35	0.24	0.27	0.26	0.17	0.07	0.22	0.21	0.28

Robust standard errors clustered by lending center is in parentheses. * significant at 10%; ** significant at 5%; *** significant at 1%. The dependent variable, social network density, is calculated by the number of links divided by the maximum number of possible links. Baseline social network data collected in November 2004. Follow-up data collected in January 2006. All regressions use fixed effect for credit officers.

Social network variables are defined as below:

- 1 Family: Have known this person since either one was a child (grandparents, parents, siblings, spouses, children, grandchildren, and cousins).
- 2 Friends: Have known this person since either one was a child (non-family members/relative)
- 3 Bought products: Have bought products or services from this person
- 4 Visit once a week: Visit this person house for social purposes at least once a week.
- 5 Knowledge index: Aggregate of 1 through 4
- 6 Given loan: Have given this person a loan outside of Bulak.
- 7 Voluntarily helped: Have voluntarily helped this person repay loans in Bulak.
- 8 Go for advice: Turn to this person for advice or help for any type of life problem; health, financial, or emotional.
- 9 Trust: Aggregate of 6 through 8
- 10 All: Aggregate of 1 through 4, and 6 through 8.

Table 11: Social Network Among Clients Who Formed Centers, New Areas
OLS

Dependent variable:	Proportion of other members in the group for whom this member knew the directions to their house	Proportion of other members in the group who were known to this members since childhood.	Proportion of other members in the group who have bought products or services from this member	Proportion of other members in the group who have given this member a loan outside of BULAK	Proportion of other members in the group who turn to this member for advise or help for any type of life problems
	(1)	(2)	(3)	(4)	(5)
Individual liability	-0.018 (0.028)	-0.199*** (0.072)	-0.064 (0.070)	0.036 (0.048)	-0.005 (0.075)

Mean of dependent variable	(0.049)	(0.098)	(0.140)	(0.103)	(0.113)
Observations	571	571	571	571	571
R-squared	0.24	0.54	0.23	0.68	0.63
Mean of dependent variable	0.94	0.69	0.62	0.21	0.42

Robust standard errors in parentheses; * significant at 10%; ** significant at 5%; *** significant at 1%. Standard errors in Columns (1) - (5) are clustered by lending centers and all regressions use fixed effect for branch. Regressions in Columns (1) - (5) includes initial members of the lending centers when they were first formed. Dependent variable in Column (6) is the herfindahl index of microenterprises among the initial members of the centers. The regression controls for the herfindahl index at the barangay level.

Appendix Table 1: Reasons for Dropout, Conversion Areas
Sample Frame Restricted to clients who dropped out from the program within the three months prior to the follow-up survey.

	Forced Out Probit (1)	Forced Out by Center or Credit Officer Multinomial Logit (2)
Dependent Variable: Forced Out		
Individual liability	-0.089*** (0.006)	
Dependent Variable: Forced Out by Center Members		
Individual liability		-0.521*** (0.032)
Dependent Variable: Forced Out by Credit Officer		
Individual liability		0.621*** (0.060)
Observations	550	550
R-squared	0.007	0.016

Robust standard errors clustered by respondents in parentheses, * significant at 10%; ** significant at 5%; *** significant at 1%. Marginal coefficients reported for the probit specifications. The omitted variable for the multinomial-logit model in column (2) is voluntary dropout. "Forced out" and "Forced out by center members" include those clients who "voluntarily" dropped out because she was embarrassed for her bad performance. Dependent variable in column 1 is a categorical variable which equals to one if any respondent reported that the client was forced out by center members or by credit officers, and zero otherwise. Dependent variable in column 2 is a categorical variable which equals to one if any respondent reported that the client was forced out by center members, equals to two if anyone reported that the client was forced out by credit officer, and zero otherwise.
