---

We would like to acknowledge the generous support of DFID in funding of the Teacher and Health Care Provider Absence Project. We are also grateful for support from Shantayanan Devarajan and Ritva Reinikka, directors of the World Development Report 2004 “*Making Services Work for Poor People*”. We would like to thank Deon Filmer and Edmundo Murrugarra for their valuable comments. We would also like to thank the participants of the *Teacher and Medical Provider Absence Workshop* in Delhi, India January 2004 for their comments. Finally, we would like to thank Sanya Carleyolson for her invaluable research assistance.

## Executive Summary

Absence of public servants from their jobs has been long discussed as an impediment to effective public service delivery. The policy dialogue on this issue has, however, been hampered by the lack of rigorous empirical studies on provider absence. We draw upon an unique survey in which we made *unannounced visits* to a sample of government run primary schools and government-aided but privately run secondary schools in Bangladesh, with the intention of:

- Documenting the extent of teacher absence
- Understand the patterns and correlates of teacher absence (including individual characteristics, facility, and community characteristics; institutional settings and practices)

### Levels and Patterns of Teacher Absence

- The average teacher absence rate in primary school is 15.5%
- The absence rate in primary schools is highest among headmasters - one out of every five headmaster was absent during the time of the survey
- Cross-sectional averages mask the extent of this problem -we find that 23.5% of primary school teachers were absent during at least one of the two visits

Our cross-section survey on secondary schools reveal teacher attendance problems which are as prevalent, if not more so compared to primary schools.

- The average secondary school teacher absence rate is 17.6%, with assistant teachers (19.3%) and headmaster (17.8%) having the highest absence rates
- The teacher absence rate in secondary schools increases with remoteness of the school: 10.8% in major metropolitan areas, 13.5% in small towns, 19% in rural areas

### Reasons Given for Teacher Absence

- The predominant reason given for why the teacher was not in school during the day of the visit was that the teacher was away performing official duties

We did not check into the veracity of the reasons given for the absence, however, in the South Asian context one often hears about the fact that government teachers are pulled away from classrooms for a variety of non-teaching related activities.

### Correlates of Teacher Absence

#### *Monitoring and Sanctions*

Teachers are 10% more likely to be absent in secondary schools which have never been visited by education officials, highlighting the importance of formal supervision. There might potentially even be a stronger informal supervision effect emanating from the community. Secondary school teachers are 68% less likely to be absent in schools attended by pupils with better educated mothers. Education level of the community is certainly related to the income level of the community, but it also reflects the level of community empowerment and interest of parents in the quality of their child's schooling, hence, a potential proxy for direct monitoring of teachers by the parents.

### *Opportunity Costs*

More “powerful” teachers will be able to protect themselves from the possibility of sanctions, explicit or otherwise, that could be brought to bear on them. We do find that headmasters are absent much more often than other teachers. Head teachers are the most powerful staff in the schools that they work. This could be an indication of their relative power but could be measuring a number of other characteristics related with outside income earning opportunities and administrative responsibilities.

Teachers who engage in private tutoring as a side occupation are less likely to be absent. This might reflect the fact that teachers might be using class time to recruit clients for their private sessions.

### *Internal Motivation/ Commitment to the Community*

Having been specifically trained in education (both pre-service training certification and in-service training) leads to better attendance among both primary and secondary school teachers, perhaps reflecting a sense of professional ethos instilled during training. Having been at one’s current job for a long time also decreases absence (which may reflect a cultivated sense of being an important part of the community). However, being recruited from the local area has no effect on teacher absence.

### **Association between Teacher Absence and Pupil Performance**

We use the extent of teacher absence as a proxy for school quality to look at the association between teacher absence and school examination pass rates; and a basic mathematics and language test that we administered to a subset of 5<sup>th</sup> and 10<sup>th</sup> grade students.

- We do not find any significant correlation between teacher absence and Secondary School Completion (SSC) examination pass rates. This does not surprise us given that the SSC exam pass rate has been remarkably stable over a long period of time, reflecting deep structural factors which we cannot control for.
- We do find that teacher absence has a significant adverse effect on English language test scores in primary schools. While we also find a negative effect of teacher absence on secondary school test scores, the effect is not significant.

### **Policy Implications: Tackling Provider Absence in Education**

***Increasing the frequency of inspections might help to lower teacher absence in secondary schools.***

Currently, while public funding to private-run secondary schools is supposed to be tied to school performance, in practice there are few institutional mechanisms to ensure accountability. Our analysis underscores the fact that greater monitoring of secondary schools must be a top priority of education officials.

***Policymakers should re-evaluate tools which are commonly touted as enhancing accountability.***

Low salaries are always blamed for causing high provider absenteeism. We, however, find that teachers with the highest salaries are more likely to be absent. Salaries already account for 97% of the overall recurrent expenditures in education – it is unlikely that the Government of Bangladesh will be able to increase that share even further. Even if new funding becomes available, education

officials should first fix this institutional problems, particularly in primary schools, which takes 20% of its headmasters away from the school on any given day.

Private service delivery does not automatically lead to better accountability. In our sample we find that private run secondary schools have comparable, if not higher rates of teacher absence compared with government primary schools. It is not about public vs. private, rather it is about strengthening the institutional capacity to hold providers accountable.

***Addressing teacher absence will require experimentation with new approaches in institutional delivery of basic services.***

Further, proper and rigorous evaluation must accompany such experiments to ensure that policymakers can identify unambiguous causal factors which help to lower provider absence. For example, while we can say that there is a strong association between lack of supervision and high teacher absence in secondary schools, we cannot make a causal argument that better supervision will lead to lower absence, without a thorough evaluation of a specific policy intervention.

## 1. Introduction

The Millennium Development Goals (MDGs) represent an unprecedented international commitment for major improvements in human development outcomes, for example, universal primary education completion by 2015. The delivery of publicly supplied schooling, however, is plagued by a plethora of problems affecting the quantity and quality of services (World Development Report 2004: *‘Making Services Work for Poor People’*, World Bank 2004a). While we acknowledge that deficiencies in schooling outcomes are influenced by a complex array of determinants (child, household and community factors, access, school quality, linkages across sectors<sup>1</sup>) – this study limits its focus to examining one specific institutional deficiency, that of teacher absence. If the teacher is absent either for ‘valid’ reasons (e.g., pulled away from classroom for non-teaching duties) or for ‘dubious’ reasons (absenteeism), *and* there is no substitute teacher available, it must go without saying that the quality of teaching will suffer.

Absence of public servants from their jobs has been long discussed as an impediment to effective public service delivery, particularly in South Asia. In certain districts of India, a recent report on primary education pointed to absentee rates among head-teachers of 33%<sup>2</sup>, and among all teachers rates so large that actual teaching was being done in less than half the schools visited (PROBE Team 1999). That report goes further and reports on gross misbehavior of teachers that do show up for work but pinpoints absenteeism per se as a major problem. A survey of primary schools in the states of Uttar Pradesh and Madhya Pradesh found that 17 % of teachers were absent from school (Rao 1999; World Bank 2001). Similarly, as survey of primary schools in West Bengal found that 20% of the teachers were absent (Sen 2002). In a large sample of public and private schools in the North West Frontier Province of Pakistan, the rate of teacher absence averaged 18 percent (Ali and Reed 1994; King et al. 1999). Another survey of primary schools in Pakistan found that 10% of the teachers were absent (Reimers 1993).

By no means is teacher absenteeism a purely South Asian phenomenon. For example, Glewwe et al. (1999) found that 28.4% of teachers were absent in one district of Kenya. Nor is teacher absence solely a developing country phenomenon (Ehrenbertg et al. 1991; Pitkoff 1993). A recent survey of studies on teacher absence concludes that while teacher absenteeism is indeed a significant problem in developed country school systems, there are few robust findings on its causes (Norton 1998). This underscores the fact that even in developed countries with a wealth of data on schools and personnel, understanding the causes of teacher absence is a difficult exercise. The problem of teacher absence in developed countries is, however, ameliorated due to the existence of a system of substitute teachers who can replace absent teachers – a luxury that few poor countries can afford.

Most of the surveys/studies mentioned above, however, are not nationally representative nor easily comparable given varying methodologies. Before the project that produced the data used in this study, there were very few nationally representative surveys of teacher absence; these included most notably a survey that found a teacher absence rate of 15 % in primary schools in Papua New Guinea (World Bank 2004b), and another that found a rate of 17 % for Zambian primary schools (Habyarimana et al. 2003). To begin to fill these gaps in our understanding of the extent and causes of provider absence, researchers from the World Bank and Harvard University<sup>3</sup>, in collaboration with the Global Development Network, initiated in 2002 a multi-country survey of service delivery facilities in basic health and education (Chaudhury et al. 2004). This project encompassed seven countries—Peru, Bangladesh, Ecuador, Ethiopia, India, Indonesia, and Uganda. The objective was

---

<sup>1</sup> Particularly the relationship between health and education (Behrman 1996; Miguel and Kremer 2004).

<sup>2</sup> PROBE team (1999)

<sup>3</sup> With primary funding from DFID

to gather data on absence using a common (and hence cross-nationally comparable) facility survey instrument in a representative national sample of education and health facilities in each country (for more details on the multi-country study, see Chaudhury et al. 2004.)

This particular study represents the first systematic examination of the issue of teacher absence in Bangladesh. The objectives of this study are to:

- (a) Document and characterize the extent of teacher absence in primary and secondary schools
- (b) Understand the patterns and correlates of teacher absence
- (c) Examine the association between teacher absence and scholastic outcomes

The rest of the paper is structured as follows. In Section 2 we highlight some pertinent institutional characteristics of service delivery of primary and secondary schooling. In Section 3 we discuss the survey methodology and dataset. In Section 4 we present some descriptive statistics on absence rates, reasons given for absences, and discuss certain key teacher, school and pupil characteristics. In Section 5 we lay out the conceptual framework, the econometric specifications, and discuss multivariate regression results regarding the correlates of teacher absence. In Section 6 we explore the association between teacher absence and test scores. Finally, in Section 7 we conclude by discussing some policy implications.

## 2. Institutional Setting of Primary and Secondary Schooling in Bangladesh

The Government of Bangladesh uses two different institutional models to deliver primary and secondary schooling. Most primary school pupils are educated in a system which is both publicly financed and publicly delivered. On the other hand, while there is considerable public financing of secondary schooling, most secondary schools are operated by the private sector.

### *Primary Schooling*

Primary education in Bangladesh officially begins at age six and is five years in length (grades 1-5)<sup>4</sup>. There are more than 76,000 primary schools in the country, and these schools are grouped into several categories (Table 1). Currently while only 49 percent of the primary schools are in the government sector, over two-thirds of the primary school students are enrolled in government schools<sup>5</sup>. The primary school system falls under the Ministry for Primary and Mass Education (MOPME). Within the MOPME, the Department of Primary Education (DPE) is responsible for the management and supervision of public primary schools. The DPE has offices located in both the district and sub-district level throughout the country<sup>6</sup>, and they are responsible for the management and supervision of formal primary education. The Directorate employs more than 175,000 teachers and oversees more than 37,000 government primary schools<sup>7</sup>. The government finances education expenditures mainly through revenue and development allocations in the national budget<sup>8</sup>. Salaries of primary school teachers account for 97 percent of the total recurrent education expenditures – making it *the* supply-side input in the production of primary schooling.

---

<sup>4</sup> Bangladesh has made tremendous progress since its independence in expanding access to primary schooling. Net enrollment rate has reached over 90 percent, with over 70 percent completion rate.

<sup>5</sup> Others schools are managed by non-governmental organizations, community organizations, or Islamic groups.

<sup>6</sup> Bangladesh is administratively divided into divisions, districts and sub-districts.

<sup>7</sup> In addition, the DPE provides technical and financial support to over 19,000 NGO and 7,000 Madrasah schools.

<sup>8</sup> Local communities often provide space in rented or donated buildings; land for school construction.

**Table 1. Distribution of Primary Schools (2000)**

Category of Institutions	Number of Institutions
Government	37,677
Non-government registered	19,253
Madrasha (Islamic School)	7,147
Satellite school	3,739
Community school	3,061
Kindergarten	2,296
Non-government unregistered	2,126
Attached to High schools	1,220
Others	145
Total	76,664

Source: DPE. 2001. Primary education statistics in Bangladesh

### *Secondary Schooling*

In Bangladesh, secondary education is divided into two levels. Secondary schools teach grades 6 - 10, and colleges provide higher secondary or intermediate level education for grades 10 - 12. The secondary schools are further subdivided into two sub-levels: lower secondary (5 – 8) and secondary (9 – 10) grades. The lower secondary level schools are known as junior high schools and are located in rural areas. Approximately 90 percent of secondary schools are operated by the private sector (Table 2). Furthermore, approximately 85 percent of secondary-level students are enrolled in non-government schools. The Directorate of Secondary and Higher Education (DSHE) is responsible for management and supervision of secondary schools, under the aegis of a separate ministry, the Ministry of Education (MOE). DSHE divides its operations into eight zones, with each zone headed by the Deputy Director, who in turn is assisted by two to four Inspectors. The District Education Officer (DEO) heads the district level offices, however, there are no permanent government staff posted at the sub-district level to monitor secondary schools.

**Table 2. Distribution of Secondary Level Institutions (1997)**

Category of Institutions	Number of Institutions
Junior Secondary	3,002
Private Secondary Schools	10,459
Government Secondary	317
Attached to College (non-government)	1,669
Madrasah (Islamic School)	4,795
Total	20,242

Source: Bangladesh Education Statistics 1997

Secondary non-government schools are legally not-for-profit institutions run under the supervision of a school management committee (SMC). These schools benefit from public financing both indirectly and directly. The Female Secondary School Stipend Project (FSSAP) provides stipends and tuition waivers to females residing in non-municipal areas attending grades 6 - 10 (with close to four million females receiving stipends annually). This demand-side subsidy program has been considered

to be immensely successful in attracting females to secondary schools (which is reflected by the fact that 55 percent of secondary school pupils are females)<sup>9</sup>. Once the secondary school manages to attract a critical threshold of students, it then becomes eligible to receive direct public subsidies. Registered non-government secondary schools receive over 80 percent of their recurrent expenses (e.g., teacher salary, rent, medical allowances) from the government. The government also makes grants to non-government secondary schools for certain capital expenditures (e.g., repair of school buildings). The remaining portion of the school's total expenditures is financed from private sources (e.g., tuition and other fees). To ensure that schools have an incentive to maintain quality, the government payments are supposed to be linked to performance criteria. Financing is supposed to stop if schools do not meet minimum performance criteria for a period of five years. In practice, once schools attain eligibility to receive financing, subsidies flow regardless of performance (Asian Development Bank 2001).

### 3. Survey Methodology

#### *Sampling*

For administrative purposes, Bangladesh is divided into six divisions, 64 districts (*Zilas*), and 507 sub-districts (*Upazilas*). Probability proportion to population size (pps) sampling was used to select 100 public primary and 100 government-aided private secondary schools for the study. First, all of the Upazilas in the country were divided into three groups: rural, municipality, and metropolitan. The samples while nationally representative, is not representative at the group-level. Fifty upazilas were picked based upon pps. In each selected Upazila, a complete list of primary and secondary schools were prepared by visiting both district and Upazila Education Offices. Then ultimately two primary and two secondary schools were randomly selected from each Upazila. All the selected primary schools were revisited; secondary schools were visited only once<sup>10</sup>.

#### *Timing of Visits*

All school surveys were carried out in 2003. There was no notification of visit given before the survey team arrived at any school. Round one of the primary schools survey was completed within March – May; round two within June – July. The secondary school survey was carried out between May – July. All schools were visited during official hours of operation. Schools were visited during days when they were officially supposed to be in session (care was taken not to visit during major examination periods). In some occasions, however, schools were found to be closed due to various reasons – such cases were not counted as ‘visits’ given that no information was recorded. During the first primary school survey round, 6 schools had to be revisited (3 schools were closed due to a local holiday; 1 school was closed due to heavy rains; 1 school was closed to throw a farewell party for the headmaster; and 1 school was closed due to the fact that all the teachers were away for training). During the second primary school survey round, 8 schools were revisited, mostly due to adverse weather conditions (6 schools were closed due to flooding<sup>11</sup>; 2 schools were closed due to teacher training). Seven secondary schools had to be revisited due to various reasons (2 schools were closed due to flooding; 2 schools were holding examinations; 2 schools were being visited by officials; and 1 school was closed due to farewell party for headmaster).

#### *Survey Instruments*

---

<sup>9</sup> Currently only 40 percent of eligible adolescents are enrolled in secondary schools.

<sup>10</sup> Due to budgetary limitations.

<sup>11</sup> One school could not be surveyed even at the third attempt given inclement weather conditions. Hence, there are only 99 primary schools in the panel.

Each sampled primary school was visited twice by a team of trained enumerators. During the first visit, the enumerators collected teacher (e.g., demographic data, location of residence, level of education, duration of posting) and school specific information (e.g., availability of latrines, distance to paved road, last time the school was visited by the DOE). For teachers who were absent both times, enumerators had to rely upon information provided by other teachers and administrators. During the second visit enumerators also collected child level information and administered a basic literacy and math exam to a subset of 5<sup>th</sup> grade students. In each primary school, ten 5<sup>th</sup> grade students were randomly picked from the student roster. Each sampled secondary school was visited only once by the same team of trained enumerators. Enumerators collected teacher, school, and pupil specific information (a basic literacy and math exam was also administered to ten randomly picked students from the 10<sup>th</sup> grade roster in all secondary schools). For teachers who were absent we again had to rely upon information provided by other teachers and administrators. Besides the facility survey, we also conducted a limited ‘institutional’ survey filled out by policymakers at the various education ministries and district education offices. Our primary focus was on collecting information governing the recruitment, posting, transfer, and supervision of teachers.

#### 4. Descriptive Findings

##### *Absence Rates*

For the purposes of this study, “absence” has a very specific definition. Upon arriving at the school, enumerators met with the headmaster, or teacher in charge if the headmaster was absent, to draw up a roster of teachers currently employed at the school. First the primary respondent was asked to go through the roster and indicate whether the teacher was present or not. If the primary respondent indicated that a teacher was absent, the primary respondent was further asked as to why the teacher was absent that day. After the interview with the primary respondent was completed, the enumerators began interviewing teachers on the roster. The definition of absence that we use throughout this study is based upon physical verification by the enumerators, i.e., a teacher is referred to as absent *only if* the enumerator could not physically find the teacher, *and* the teacher was away due to reasons given other than suspension, deputation (‘temporary’ reassignment), or working on a different shift (teachers belonging to these three categories were completely removed before conducting any analysis, i.e., they neither count as being present or absent).

We present the basic results concerning primary school teacher absence in Table 3. The teaching staff in primary schools consists of three types of teachers - headmasters, assistant headmasters, and (regular) teachers. Given the extremely small proportion of assistant headmasters in most primary schools, we lumped assistant teachers with teachers. Out of 413 teachers (all types) in our sample, 12 teachers were on suspension, deputation, or worked in a different shift. Thus, our effective sample of primary school teachers was 401. Out of the 401 teachers, the absence rate (averaged over two rounds) is 15.3%. Headmasters had the highest absence rate - one out of every five headmaster was found to be absent. Absence rates are highest in schools located in major metropolitan areas (17.5%).

Comparing with other countries in the global project and those for which we have comparable surveys (see Table 3.1), Bangladesh ties with PNG for the third-lowest absence rate in our sample. The absence rate is low compared to the only other (richer) South Asian country in our sample, India (25% - average over 14 states)<sup>12</sup>. The Bangladesh primary schooling system, however, has one of the lowest teacher-to-pupil contact time and one of the highest pupil-to-teacher ratio in the developing world (ADB 2001). While an average (across two visits) absence rate of 15% does not seem too

---

<sup>12</sup> The teacher absence rate in Bangladesh is also low compared to bordering Indian states surveyed under the Absence Project: West-Bengal (23%) and Assam (34%).

high, it is important to note the 23.5% of teachers were absent during at least one of the two visits<sup>13</sup> (we can compute this figure given that we track the same schools and teachers across the two survey rounds). This implies that the effective pupil-to-teacher ratio is actually higher given that almost one out of every four teacher is potentially absent.

We present the basic results concerning secondary school teacher absence in Table 4. The teaching staff consists of four types of teachers - headmasters, assistant headmasters, teachers, and assistant

	Absence rate (%)
Bangladesh	15
Ecuador	14
India	25
Indonesia	19
Peru	11
Papua New Guinea	15
Uganda	27
Zambia	17

*Sources: Chaudhury, Hammer, Kremer, Muralidharan, and Rogers 2004 for most countries; NRI and World Bank 2003 for Papua New Guinea; Habyarimana, Das, Dercon, and Krishnan 2003 for Zambia*

*Note: Absent staff are fulltime teachers on current shift who were not found anywhere in the school at the time of an unannounced visit (see text for details).*

teachers. Out of 959 effective teachers in our sample, the absence rate is 17.6%. Assistant teachers and Headmasters had the highest absence rate (19.3% and 17.8%, respectively). While there appears to be no relationship between income-level of the division and teacher absence rate, within divisions, absence rates increase as you move out from major towns (10.8%), to peri-urban (13.5%), to rural areas (19%). This is an interesting finding given that parallel labor market opportunities and higher income earning potentials germane for teachers decrease as you move from the center to the periphery. Rural secondary schools, however, are less likely to be supervised by education officials, and hence, teachers would be more likely to shirk. Also, as we mentioned earlier, there are no secondary school supervisors below the district level.

Unlike primary schools, in secondary schools female teachers are more likely to be absent (21%) relative to their male colleagues (17.1%). While in this section we hold off in drawing upon any conceptual framework to discuss these descriptive statistics, we would like to note that the (overall average) absence rates for primary and secondary schools teachers are quite similar. By no means does private provision automatically guarantee better accountability.

It is interesting to note that, of the teachers who were present at the school on the day of the interview, only 43% of primary school teachers and only 38% of secondary school teachers were actually found to be in teaching. The rest were mostly out of class (but in the school) on a scheduled

---

<sup>13</sup> Only 3.2% of teachers were absent during both survey rounds.

break or carrying out administrative tasks. Thus, teaching was actually being done is less than half of the schools visited. Teachers are certainly not supposed to be holding class each and every minute that they are in school, however, these low figures of teachers who were actually teaching comes as a surprise. Again, this is an issue that requires further investigation with more specifically detailed survey modules on time use within schools.

## Primary School Absence Statistics

Number of Schools in the Sample:	99 (each visited twice)
Number of Teachers in the Sample:	401 (802 observations in the panel)
% Teachers Absent (average):	15.3
% Teachers Absent – Round 1:	16.1
% Teachers Absent – Round 2:	14.5
% Teachers Never Absent:	73.4
% Teachers Absent Once:	23.5
% Teachers Absent Twice:	3.2

### % Teacher Absent

Male	15.3
Female	15.3
Head Master	20.2
Teacher	14.9
Rural	15.7
Municipality	12.7
Metropolitan	17.5
Barisal	10.3
Chittagong	14.3
Dhaka	15.5
Khulna	15.4
Rajshahi	14.3
Sylhet	18.5

## Secondary School Absence Statistics

Number of Schools in the Sample:	100
Number of Teachers in the Sample:	959
% Teachers Absent:	17.6

	<b>% Absent</b>
Male	17.1
Female	21.0
Head Master	17.8
Assistant Head Master	11.3
Teacher	15.2
Assistant Teacher	19.3
Rural	19.0
Municipality	13.5
Metropolitan	10.8
Barisal	15.3
Chittagong	13.8
Dhaka	19.6
Khulna	13.0
Rajshahi	21.3
Sylhet	19.0

### *Reasons Given for Absence*

The various reasons given for teacher absence are presented in Table 5. During the pilot survey we did attempt to look at leave records and other evidence to corroborate reasons given for absence. Usually such probing was considered too intrusive by the respondent and considerably slowed down the survey. We decided not to probe further into this issue during the actual survey. Thus, it is important to bear in mind that we cannot make any judgment regarding the veracity of the reason given as to why the teacher was absent from school that given day.

While only less than 2% of the primary school teacher absences were unaccounted for (i.e., no excuse could be given whatsoever), 20% of the absences of secondary school teachers could not be accounted for at all. The two predominant reasons given for primary school teacher absence was “away on official school related duties” (49%), and “on official-leave” (33%). In secondary schools, 39% of the absences were supposedly due to teachers having to perform official duties away from the school, and 22% of the absences were supposedly due to personal leave. In the South Asian context, one often hears about public school teachers who are pulled away from classrooms to partake in all sorts of government duties ranging from helping to conduct population census to immunization campaigns, to assisting local politicians in various capacities<sup>14</sup>. Regarding the issue of being away “on official-leave”, even if these teachers are genuine on leave, it is surprising that so many teachers would be on leave while school was in session.

### *Basic Teacher, School, and Pupil Statistics*

Teacher, school (infrastructure, supervision), and pupil characteristics are presented in appendix Table A1. The only significant demographic difference between primary and secondary school teachers appear to be that primary school teachers are more likely to be female. It is not surprising that given the difference in basic education requirements between primary and secondary schools, secondary schools are more likely to have teachers who are college graduates. Secondary schools also tend to be newer facilities with better infrastructure. Given as we previously mentioned that there is no provision for sub-district secondary school inspections, it does not come as a surprise that 15% of secondary schools have never had an inspection visit, compared to less than 1% of primary schools who have never been inspected.

We are encouraged by the fact that some of our sample averages are consistent with national statistics. While provision of public primary schooling in Bangladesh is quite progressive, most of the benefits of publicly-aided secondary schooling are captured by the rich<sup>15</sup>. In our sample we find that pupils attending secondary schools come from families with better educated parents who own more assets, relative to pupils coming from primary schools. Despite the fact that potentially all females are eligible to receive the secondary school stipend, it appears that the ‘costs’<sup>16</sup> of sending a child to secondary school still deters poor households from doing so. While we do not present gender-differentiated averages on parental background, we find that in secondary schools female

---

<sup>14</sup> Government-aided secondary schools by law have to allow the local member of parliament to sit on the school management committee. Often one hears about local politicians who exert their influence over the SMC for their own personal agendas.

<sup>15</sup> While the poor account for 56% of the primary education expenditure, the rich capture 76% of the secondary school expenditure (*Bangladesh Public Expenditure Review*, World Bank 2003).

<sup>16</sup> Besides loss of potential wage income, for females there are other issues such as domestic work, social norms, and concerns about safety, that hinder their parents from sending them to school.

**Table 5. Primary and Secondary Schools: Reasons for Absence (%)**

*Overall (All-types of Teachers)*

	<b>Primary</b>	<b>Secondary</b>
Official teaching related duty	49.0	39.1
Official non-teaching related duty	4.5	0
Sick	9.5	9.5
Authorized leave	32.8	21.9
Left early	0.7	2.4
Arrive later	1.5	0
Off due to examinations	0	7.1

pupils are more likely to come from households with high value assets (e.g., TV), relative to male students. Again, this is a possible indication that the subsidy is being captured by females from non-poor households. Putting aside the benefit-incidence dimension, the secondary school stipend program has boosted female enrollment which is reflected by the fact that 55% of secondary school pupils in Bangladesh are females - which mirrors the proportion in our secondary school sample. Another example of the representativeness of our sample is that our average secondary school leaving examination pass rate (39.5%) lines up with the national average (40%).

## 5. Empirical Model of Teacher Absence and Regression Results

We know from derived demand theory that goods are valued along both quantity and quality attributes (Lancaster 1966). As long as parents view teacher absence as a negative attribute, are able to bear the cost of switching schools, and there is no rationing of good quality schools, parents can 'shop' around till they find a school with lower absence rate. If enough parents voice their concerns and exit out of dysfunctional schools (a la Hirshman 1978), over time we would expect overall schooling quality to improve. It is, however, extremely difficult to model the behavior of public sector employees (complex political-economy processes, nested principle-agent problems) which yield reduced-form solutions with testable empirical hypothesis (Dixit 1997). In principle at least, it should be easier to model the behavior of secondary school teachers given that modeling the private provision of schooling should be no different than modeling the private provision of samosas<sup>17</sup>. However, these are not purely private providers given that they are employees of 'not-for-profit' entities who operate under substantial public subsidies and various political-economy considerations.

While we appreciate the complexity of these relationships, the purpose of this section is more modest - to empirically examine certain correlates of teacher absence. In that endeavor we highlight four types of factors that could influence whether a teacher show up for work on any given day:

1. the opportunity cost of time;
2. the actual costs of getting to work on any particular day;
3. the sanctions they can expect if they do not show up for work
4. their own internal sense of responsibility towards their fellow colleagues; to the community they serve.

The set of variables available in our data which we use as proxies are listed in Table 6, and are matched to the underlying factors we believe they represent.

---

<sup>17</sup> A common South Asian snack.

**Table 6. Matching variables to factors influencing costs and benefits**

	Opportunity costs	Accessibility	Sanctions	Intrinsic motivation
Rank/Salary Scale (e.g., headmaster versus other teacher)	✓			✓
Education (schooling and certification)	✓			✓
Experience	✓			✓
Tenure	✓			✓
Gender	✓	✓		✓
Residence (proximity to work)		✓		✓
Infrastructure level of the Area in which the School is located	✓	✓		
School Infrastructure				✓
Supervision by Education Officials			✓	
Parent's Education/Wealth	✓		✓	
Parental involvement in Schooling			✓	

Note that most variables have multiple influences on factors which ultimately shape a teacher's decision to show up for work. Take for example the education/wealth level<sup>18</sup> of the parents. Holding all other factors constant, teachers have higher earning opportunities in richer areas, and hence are more likely to skip out of class. On the other hand, if teachers perceive richer parents to have a stronger 'voice' in holding providers accountable (e.g., politically connected; are more involved in child's schooling), they are more likely to show up to school. We cannot discern, a priori, which countervailing effects will dominate.

Besides the cluster of variables mentioned above, we control for other covariates related with demographics (e.g., marital status) and regional effects (which could proxy for a variety of factors ranging from wealth, to infrastructure quality, to level of supervision).

### *Regression Results*

We present the primary school random-effects probit regression results in Table A3<sup>19</sup>, and the secondary school probit regression results in Table A5. Since several right-hand side variables are potentially endogenous, we estimate one specification (column 1) without including some variables which are most likely to be endogenous (e.g., whether or not the teacher also works as a private tutor), and another specification which includes all the variables (column 2)<sup>20</sup>. Instead of discussing Tables 7 and 8 variable by variable, we discuss several broad results along the factors which influence

<sup>18</sup> We do not have information on household or community wealth. We use asset holdings of pupil's parents as a proxy for wealth.

<sup>19</sup> We only present the random-effects probit specification for the primary school analysis given that probit specification results are essentially identical.

<sup>20</sup> The regression variable means are presented in Appendix Tables A2 and A4.

a provider's decision to show up to work any given day. Again, we refrain from making any causal interpretations given that at best we can highlight the correlation between teacher absence and some specific factors.

### *Opportunity Costs*

Primary school teachers who engage in private tutoring as a side occupation are less likely to be absent. This might reflect the fact that teachers might be using class time to recruit clients for their private sessions.

It is interesting to note that secondary school teachers who work in schools which are near a train station are 20% more likely to be absent. Proximity to a train station might be associated with wealthier areas with potentially higher parallel labor market opportunities. School proximity to a bus-stop, however, seems to reduce teacher absence. We cannot reconcile these two effects without further information on what modes of transportation are used for what specific purposes (commuting from home to school, commuting from school to other work place).

### *Logistics*

A common complaint among providers, particularly female providers, is that appropriate/safe housing is unavailable in rural areas. Our results, do show that primary school teachers who live near the school are less likely to be absent. Many factors, of course, contribute to decisions about where to live and when to commute, most of which are hard to observe. Indeed, our crude measure of how far one lives from the school does not capture many of the variables (amenities, quality of social relations) that could influence daily decisions on top of the choice of place of residence.

### *Monitoring and Sanctions*

Teachers are 10% more likely to be absent in secondary schools which have never been visited by education officials<sup>21</sup>. Furthermore, if a senior school official has gone for a visit to meet with education officials within the last two months, a teacher from that school on average is 30% less likely to be absent. This highlights the importance of formal relationships between education officials and schools that they are supposed to supervise.

There might potentially even be a stronger informal supervision effect emanating from the community. Secondary school teachers are 68% less likely to be absent in schools attended by pupils with better educated mothers. Education level of the community is certainly related to the income level of the community, but it also reflects the level of community empowerment and interest of parents in the quality of their child's schooling, hence, a potential proxy for direct monitoring of teachers by the parents. This is further reinforced by the fact that teachers are 27% less likely to be absent in schools where there has been a PTA meeting with the last two months.

More "powerful" teachers will be able to protect themselves from the possibility of sanctions, explicit or otherwise, that could be brought to bear on them. Head teachers are the most powerful staff in the schools that they work. We, however, do not find that headmasters are more likely to be absent in the multivariate analysis.

---

<sup>21</sup> We have previously mentioned that unlike the governance of primary schools, there are no permanent government staff posted at the sub-district level to monitor secondary schools. In our sample this is manifest by the fact that while only 15% of primary schools have never been visited by the ministry, 59% of secondary schools have never been visited by the ministry.

### *Internal Motivation/ Commitment to the Community*

Having been specifically trained in education (both pre-service training certification and in-service training) leads to better attendance among both primary and secondary school teachers, perhaps reflecting a sense of professional ethos instilled during training. For example, secondary school teachers who have never attended a training program since joining the school are 16% more likely to be absent.

Having been at one's current job for a long time also decreases absence (which may reflect a cultivated sense of being an important part of the community). However, being recruited from the local area has no effect on teacher absence.

## **6. Association between Teacher Absence and Test Scores**

While there are no internationally comparable test scores from primary or secondary schools in Bangladesh, some of the rare studies on schooling achievement suggest that many students complete schooling without having acquired basic mathematical, reading or writing skills. For example, Greany et al. (1999) found that 70 percent of students in their sample who had completed fifth grade were not minimally competent in writing. Apparently quality also varies by type of school management. A BRAC report finds that low-cost (per-unit) NGO schools manage to produce better achievement results than higher-cost public primary schools (cite BRAC). Comparability is however, not so straightforward given that the pupil cohort attending private/NGO run schools is potentially different than those attending public primary schools (e.g., many students attending BRAC schools are older students who had dropped out of the education system and are now going back to school; differences in motivation, ability).

There is serious concern that the quality of government-aided secondary schools is dismal. On average 40% of students pass the secondary school leaving examination. A recent study by the Government of Bangladesh (cite GoB) shows that some government-aided secondary schools continue to receive funding despite being unable to produce a single pupil who can pass the exam<sup>22</sup>. Besides pass rates, we know virtually nothing about what pupils actually learn in these secondary schools (in terms of mathematical/literacy skills). Another widely held belief is that government managed secondary schools are better than government-aided private schools. The public sector manages (aids and delivers) some excellent secondary schools which are referred to as 'model' schools. These secondary schools are located in the district headquarters and are meant to serve as models of excellence to be emulated by other schools in the district. Given that the public sector can focus its resources and management effort on operating only a few of these elite secondary schools, again akin to primary schools, makes it difficult to compare school quality between public and private managed secondary schools (Asadullah 2004). Anyway, we do not have government managed secondary schools in our sample, nor do we have private/NGO managed primary schools in our sample. Given the data that we do have, we can explore the impact of teacher absence on certain measures of school achievement within public primary and government-aided private secondary schools. We use average teacher absence in the school to proxy for accountability and institutional oversight. Unlike the analysis in the previous section where we were averse towards assigning causality, in this case we are more comfortable about the direction of the effect. It is unlikely that low test scores lead to higher teacher absence, rather we can make a reasonably strong argument that teacher absence should adversely affect student learning.

---

<sup>22</sup> We only have one such school in our sample.

In primary schools grade progression is virtually automatic, so there is no reason to examine the effect of teacher absence on primary school leaving examination rates (furthermore, there is essentially no variation in our sample). Secondary school completion examination (SSC) pass rates have remained remarkably constant over a long period of time in Bangladesh. There are deep structural factors which we will certainly be unable to control for given the limited information in our survey. Furthermore, the SSC pass rate is at the school level, hence our regression sample would be quite small. It is not surprising that we do not find any significant results regarding SSC rates (results are not reported). Our main focus in this section is on relating the incidence of teacher absence, as crude proxy for overall school quality, on outcomes from a basic mathematics and literacy test that we administered on a random subset of 5<sup>th</sup> and 10<sup>th</sup> grade students.

We would like to stress the point that the primary objective of this study was to document the extent of teacher absence, not to establish causal relationships between the determinants of teacher absence and the impact of teacher absence on test scores. To properly examine the causes and consequences of teacher absence, will require detailed panel data information of teachers, their respective students, their specific test scores, family backgrounds, and community characteristics. We hope that this study can highlight several important issues which should be thoroughly examined in future studies.

### *Mathematics and Language Test*

We present the primary school pupil performance results in Table A7<sup>23</sup>. Teacher absence has a detrimental effect on the English language tests. A one percent increase in (average) teacher absence leads to a 38% reduction in the likelihood that the pupil will correctly answer the English writing test; while a one percent increase in the teacher absence rate leads to a 67% reduction in the likelihood that the pupil will correctly answer the English reading test.

Pupils with uneducated mothers are 7% less likely to correctly answer all the multiplication questions; while in general pupils with uneducated parents are less likely to be able to correctly answer the English writing and language test. Pupils with older mothers are less likely to pass the English reading test, possibly reflecting the fact that older mothers are less likely to be exposed to English. We do find a strong effect of parental involvement in child schooling - parents who have met with the teacher within the past month of the survey are 7% more likely to pass the English writing exam. Interestingly we notice an adverse sibling effect which could potentially proxy for resource/parental time constraints. Pupils who live close to the school are 7% more likely to pass the addition test. Pupils who come from homes which own a clock and a bike, are 12% and 8% more likely to correctly answer the English reading test, respectively.

Larger class-size has an adverse effect on the English language tests, while it increases the likelihood of correctly answering the multiplication test. The class-size and student performance relationship is one of the most thoroughly examined and yet still unresolved relationship in the schooling literature, hence, we desist from discussing this effect any further. Pupils coming from schools which have separate toilets for female students are 6% more likely to correctly answer the multiplication test, and pupils belonging to schools which have drinking water are 5.6% more likely to correctly answer the addition test, the other school infrastructure variables have conflicting effects. Surprisingly, pupils coming from rural schools are more likely to correctly answer the multiplication test, while pupils coming from metropolitan schools are more likely to correctly answer the addition test. Pupils coming from Dhaka and Chittagong, the two most affluent and modernized districts, are not surprisingly more likely to correctly answer the English language tests.

---

<sup>23</sup> Variable means are presented in Appendix Table A6.

We present the secondary school pupil performance results in Table A10<sup>24</sup>. Even though teacher absence has the expected negative effect on 3 out of the 4 test, none of the effects are statistically significant. We do, however, find strong pupil, family background, and location effects. Male pupils are more likely to do better in the mathematics tests, while female pupils are more likely to do better in the English reading test. While female pupils in our sample fared better in the English tests, surprisingly pupils who come from schools with a high fraction of female students are less likely to correctly answer the English language tests.

Pupils with better educated parents are more likely to pass the English writing test. Similar to the primary school results, we also find a strong effect of parental involvement in child schooling - parents who have met with the teacher within the past month of the survey are 6% more likely to correctly answer all the questions on the multiplication test. Pupils who come from households which own a radio are 10% more likely to correctly answer the English reading test. This could reflect both household wealth effects and also greater exposure to English via the radio. While pupils coming from schools which have drinking water are 16% more likely to correctly answer the addition test, and pupils belonging to schools with working electricity are 12.5% more likely to correctly answer the addition test, the other school infrastructure variables have conflicting effects. There are strong, and surprising location effects. For example, pupils coming from Dhaka schools are less likely to correctly answer the addition and English writing test – which seems quite improbable.

## 7. Policy Implications

We draw upon an unique survey in which we made unannounced visits to a sample of government run primary schools and private run (government-aided) secondary schools in Bangladesh with the intention of documenting the fraction of teachers who were actually present at the school. The survey represents the first attempt to quantify the extent of this problem on a nationally representative scale in Bangladesh. Besides contributing to the nascent empirical literature on provider absence, this study highlights the fact that service delivery problems stemming from problems related to misalignment of incentives and lack of accountability, cut across both the public and private sector.

The following discussion on policy implications below must be tempered with the fact that the correlations that we have found between teacher absence and other variables of interest are just that—correlations, and not causal relationships. Most of the variation in our data is cross-sectional rather than time-series, and moreover, we do not have important exogenous factors that would allow us to identify causal pathways.

One often hears about various policy prescriptions which will supposedly usher in better accountability and reduce shirking by providers. This study has allowed up to examine three such prescriptions:

### *(1) Need to increase salaries*

In primary schools we find that the absence rate is highest among headmaster who are the highest paid staff in the school. So in primary schools, our immediate focus should be on finding out if there are really official reasons which interfere with the workday of headmasters rather than on their salary. Salaries already account for 97% of the overall recurrent expenditures in education – it is unlikely that the Government of Bangladesh will be able to increase that share even further. Even if new funding becomes available, the Government of Bangladesh should

---

<sup>24</sup> Variable means are presented in Appendix Table A8.

first fix this institutional problems which takes 20% of its headmasters away from the school on any given day. We do at least have some basis for a salary argument in secondary schools where the absence rate is highest among the lowest paid category of staff (assistant teachers) – the second highest absence rate is still among headmasters (the highest paid category of teachers). While in public schools we have less dispersion in terms of staff categories (one headmaster, the rest being regular teachers), there are sharper wage differentiated categories in secondary schools. There might be a problem of moral in having low-paid assistant teachers (with limited opportunities to climb up the career ladder) working along higher paid teachers, assistant headmasters, and headmaster.

(2) *More teacher training*

The international experience of the impact of teacher training on staff quality and schooling outcomes is quite weak, and if anything it has been shown to be an ineffective policy tool in South Asia (World Bank 2004a). We do, however, find that secondary school teachers who have never received any training since joining the secondary school are 16% more likely to be absent. Furthermore, both primary and secondary teachers who have gone through a teacher training certification program before joining the school are less likely to be absent. We need a better understanding (particularly within the Bangladeshi secondary school context) of the various types of training available for teachers, how teachers are selected for training, whether or not that selection is linked with other performance criterion, and what are the specific components of the training module that may help to boost staff motivation. Even if better teacher training does lead to increased teacher accountability in secondary schools, we should schedule training so that it does not pull away teachers from class rooms (teachers would have to agree to undergo training when school is not in session).

(3) *Leave it to the private sector*

The dysfunctional track-record of public service delivery in many developing countries should not serve as ideological fodder for privatization. Some developed countries such as France have well functioning public primary school systems while other developed countries such as The Netherlands have equally well functioning private managed (but government-aided) primary school systems. In our study we could not compare differences in management within schooling level (e.g., government run primary schools vs. private run primary schools). We have pointed out that even if we had such data, comparison might be difficult given the fact that cohorts/schools might not be comparable (e.g., a few elite ‘model’ government run secondary schools vs. a horde of private managed secondary schools which have been set up for a variety of reasons<sup>25</sup>). Anyway, most primary school students attend government run schools, while most secondary school students attend private run (government-aided) schools. What we can point out, however, is that the private sector does not automatically lead to better accountability. In our sample we find that private run secondary schools have comparable, if not higher rates of teacher absence compared with government primary schools. It is not about public vs. private, rather it is about strengthening the institutional capacity to hold providers accountable. What we could benefit from are rigorous political-economy studies which pry into the nature of incentives facing a variety of actors ranging from national and sub-regional policymakers, school administrators, to front-line teachers.

If we could highlight a specific type of intervention, we would like to note that ***increasing the frequency of inspections might help to lower teacher absence in secondary schools.***

---

<sup>25</sup> Doctors often vigorously campaign for membership in the school management committees where they can use their position to cultivate clients.

Currently, while public funding to private-run secondary schools is supposed to be tied to school performance, in practice there are few institutional mechanisms to ensure accountability. Our analysis underscores the fact that greater monitoring of secondary schools must be a top priority of education officials. Again, it would be ideal if we could rigorously evaluate the impact of a specific policy intervention to increase school-level supervision on changes in teacher absence rates.

**Table A6. Bangladesh: Primary School Student Regression Variable Means**

***Test Results***

Correct Multiplication	84.4%
Correct Addition	86.3%
Correct writing English	30.5%
Correct reading English	40.9%

***Student Family Background Characteristics***

Father has no education	30.8%
Father has no formal education	25.3%
Father's age	43.3
Mother has no education	39.7%
Mother has no formal education	29%
Mother's age	35.4
Number of siblings	4
Boy student	47.1%
Child lives <= 1km	87.8%
Pukka	4.8%
Radio	40.6%
Chair	77.8%
Clock	80.8%
Bike	35.5%

***Teacher and School Characteristics***

Teacher is absent	16.1%
Student to teacher ratio	70.9%
% Female Students	51.1%
Parent-teacher meet<=1 month	59.4%
Separate toilets Female Students	41.5%
Drinking water	77%
Electricity	28.7%
Playground	76.7%
Fans	29.3%

***Community Characteristics***

Rural	76.9%
Municipality	14.8%
Division: Barisal	10.6%
Division: Chittagong	19.4%
Division: Sylhet	4.3%
Division: Dhaka	24.8%
Division: Khulna	13%

**Table 10. Primary School Student Test Regressions**

Probit Regression Results from 4 Tests: Multiplication, Addition, English Writing, and English Reading. Dependent variable takes on the values: 1 = If Pupil Correctly Answered the Test; 0 = Otherwise; (note coefficients reported as marginal probabilities)
